Ok, here's a little help! ;-)

The maths in the spec is logically correct, yet the result it gives has a small error compared to what is coming out of the "official" programs. There aren't too many ways that could happen with such a relatively simple calculation.

One obvious possibility is that the numbers 380972 and 190486 (which is 380972/2) are incorrect. Now if I change 380972 to 380927, I get almost the same answer as the "official" programs. There's still a small difference, but I have a good idea why that might occur.

So, I think a good starting point would be to find out whether the "official" programs are using 380972 or 380927...

I believe that this sort of function should include some sample
code in the specification.

A pair of C functions, encode, and decode would be nice.
This is how it is done in a lot of the RFC's (Internet standards)

Without having the source code for the "official" programs, the small
difference in the least significant digits makes me suspect that some
part of the calculation has been done in (single precision) floating
point, which has a precision of 6-7 digits. As a result, any digits
after the 6th or 7th are useless.

If the result is to be displayed with 1/100 minute resolution, it
would be natural to use an internal representation in which the 1/100
minute corresponds to an integer value of 1 (or 1.000 if someone
insist on using floating point values). In a binary floating point
representation, you can not express values like 2.01 exactly, but with
plenty (1-3 bits) of extra resolution, the displayed value can be
rounded and displayed correctly to two decimals.

Maybe this will help...

The key numbers in my code are 4186 * (90-LAT)
and 2093 * (LON-180)

Where LAT and LONG are in decimal degrees. This gives the first 3 digits of the `YYY_XXX_` value. The last digit in X and Y are then just one 91th of the remainder.

Notice that if you divide 380972 by 91 you get 4186.5xxxx
But we used instead 380926 which is the product of 4186 and 91

The reason for this was that positions to `YYY_XXX_` can all be done with single precision integers and get you to a pretty good accuracy of about 100 feet worldwide (comparable to DD MM.HH) If you want to take the remainder and divide it by 91, then you can get precision down to about 1 foot. But we did not want to burden Pic processors with double precision integers where positional accuracies to the nearest 100 feet were good enough..

Hope that helps...
Bob

As several people have commented, it turns out that the spec covering encoding/decoding of compressed posits is (slightly :-)) wrong.

Refer to page 32 of the APRS Protocol Spec, draft version 1.0.1g, dated 3 December 1999 (at <http://www.tapr.org/tapr/html/Faprswg.html>).

In the "Lat/Long Encoding" section, the computations should be:

YYYY is $380926 * (90 - \text{latitude})$

XXXX is $190463 * (180 + \text{longitude})$.

In the "Lat/Long Decoding" section, the same big numbers are used as the divisors:

Lat = $90 - ((\dots\dots\dots) / 380926)$

Long = $-180 + ((\dots\dots\dots) / 190463)$

Using these numbers, the examples computed by Bob Bruninga and Brent Hildebrand in other threads on this list match correctly.

The longitude encoding/decoding examples in the spec will obviously have to be reworked. For now, this is left as an exercise for the reader ... (and if you decide to have a go, please let me know what you get for the 4 ASCII characters for 72.75 deg W). Hopefully I will get the same!

73

Ian, G3NRW

Technical Editor, APRS Protocol Specification

So, presumably, all the APRS applications that could handle compressed posits at the time the spec was drawn up use your approximation? In that case, why does the spec not reflect that situation? I have seen it said enough times that the spec is supposed to be documenting the current situation. (That's a question to the WG in general, not specifically to Bob.)

If the same compressed posit is decoded by a program that uses the above approximation and one that faithfully follows the spec (including using sufficient precision to avoid intermediate rounding errors), the difference in position is about half a mile in the USA, and over a mile in some other parts of the world. That doesn't seem a very satisfactory situation when "Improved position to 1 foot worldwide" is claimed.

I get <*e!

Also for your entertinament, you will notice that the SIGN of the math for longitude is backwards from what you might have expected. This was done early on so that all the English Language Swear words did not plot to locations in the middle of the USA...

I dont know where they ended up, but at least they aren't in our backyard... <grin>...

I could see the joy that APRS'ers would have driving circles around the point that produced the worst possible cursewords...

I think I moved them to the middle of the oceans...

bob, WB4APR

Ian,

If it is not possible to rework the spec document to correct errors and ambiguities, could an error or erratta document be posted along with the APRS101g.pdg file?

Many of the document errors have been discussed on the sig, and corrections offered, but these are not readily available to those who may wish to use the document to write new, or to correct existing APRS applications.

Presently, the chapter 9 - Compressed Postion Report Data Formats, chapter 10 - Mic-E Format, and chapter 11 - Object and Item Reports seem to be causing the most confusion.

Bill KC9XG

Gosh Roger. The spec was wrong. Thanks for bringing this up.
We are so very sorry for any inconvenience we may have caused you...

But I would not be surprised if there are not other errors in the spec also. REMEMBER, it was written after the fact to document what is in APRSdos and the other programs. Thats over 40,000 lines of code in APRSdos alone that you are trying to duplicate.

I think the current process of finding errors and omissions in the after-the-fact documentation and correcting them is about the best we can do. Obviously you think there is a better way. Maybe you would share with us how you think we can do this better...

bob

Point taken Bill. In fact, the Working Group now have in their possession the updated version of the spec, incorporating all the feedback from everyone since December.

Hopefully there are only a few minor tweaks outstanding, and they will

sign it off for public distribution "real soon now".

I know it's been a long wait, but there was a *lot* of feedback on the last draft -- the hardcopies are in a folder 2 inches thick! Not only corrections, but also some hitherto obscurely documented features which somehow didn't find their way into the December draft.

Several chapters have been much expanded/re-written (notably the Mic-E chapter) to make things a lot clearer -- the whole document has grown a further 20 pages, and is now up to page 113.

BTW is here a version of APRS dos and Winaprs and Mac APRS that are the versions version 1 of the standard is trying to match.

As time goes on What these applications do changes.

I just want to be confident that the spec is not trying to track a moving target.

Charles

Well, in 20 years of writing software, I've never made a mistake, so I
really don't know what you people are doing... ;-))
(for the humour-challenged, note smiley!) ^^^

Sorry to have irritated you... I read your message as giving good
reasons why you had chosen to do things differently to what the spec
said, not as saying that there was an error in it. So I couldn't really
understand why the spec didn't reflect your method. That was my only
point. Obviously I misunderstood what you were saying.

One thought that immediately comes to mind is to invite him to join the APRS-WG. He is the author of a popular APRS program, just seems logical to me to have him in the WG from the start.

Yes, I know he has stated in the past he would not join, but more often then not a little sincere interest goes a long way in changing peoples minds.

Well, back on Email, and I see Bob has pointed out where the problem in the spec is and I'm sure Ian will correct it. The Spec shows the "best" that Base91 can do. Bob's modification to my algorithm was to fix some math problem he had. I did not like esthetically, but it is close enough.
For testing purposes, Here are what the end points should calculate out to:

The algorithm as implemented on-air.

```
0 0 => NN!!NN!!  
S90 W180 => {{!!!!!!  
N90 E180 => !!!!{{!!
```

The algorithm as noted in the Spec (and as originally proposed and now wrong)

```
0 0 => NNNNNNNN  
S90 W180 => {{{{!!!!  
N90 E180 => !!!!{{{
```

Nice symmetry. <sigh> :)

APRS+SA decodes it as encoded by APRSdos, but does not encode it, and I have no plan to encode it at this time.

In article <LYR14779-80521-2000.04.28-17.43.36--Ian.Wade#care4free.net@list
s.tappr.org>, Brent Hildebrand <bhildebrand@earthlink.net> writes
>Well, back on Email, and I see Bob has pointed out where the problem in the spec
>is and I'm sure Ian will correct it.

That is now done, as I detailed in another thread yesterday.

>For testing purposes, Here are what the end points should calculate out to:
>
>The algorithm as implemented on-air.
>0 0 => NN!!NN!!
>S90 W180 => {{!!!!!!
>N90 E180 => !!!!{{!!
>

I confirm that using the new encode/decode constants (380926 and 190463)
these character strings are correct.

That is, the next (RSN) release of the spec will agree with existing on-air
data.

[Also, following Bob's decision to make western longitudes negative to
avoid rude words, I can confirm that the 8-character compressed posit
"rudeword" is close to the Balleny Islands in the Ross Sea, Antarctica, and
that "RUDEWORD" is at the north end of Lake Malawi in East Africa ...]

My appologies too. I was at the end of a very long day and behind on everything I was committed to. Was trying to answer all the mail.. Now things are back to their normal frenzied pace.

So please feel free to speak up when anything built by the spec doesn't

match APRSdos. Such discrepancies do need to be addressed. The point that the spec is an after the fact condensation of my 800K of readme files which themselves are a 2nd order documentation of the code is a mechanism that may miss some details.

Authors,

Actually, I may be the source of this problem. If you are using my INITxxx.TNC files in your distributions, then that is why your software is not initializing TNC's MYALIAS to RELAY. Since APRSdos code itself does the MYALIAS RELAY, this means that the INITxxx.TNC files DO NOT..

Thus if you relied on them to do most of the default initializations, then

this explains why your stations are not getting configured to RELAY.
May I suggest that you insert the line

MYALIAS RELAY in all of your INITxxx.TNC files

and in the INITKAN.TNC that you include

UIDIGI ON RELAY

Thanks. This simple change will restore the fundamental RELAY structure throughout APRSdom. Notice that this issue is independent of the arguments for and against having the RELAY ALIAS at DIGIS... That is a separate subject and should not affect our defaults of RELAY at all home stations. Thanks

Bob

No, thats not historically correct. Brent proposed a variety of base 91 system that got hammered down to a YYYXXX system. We all implemented it for testing. But Steve made the good point that it just needed more precision. We added one more byte that included 3 bits of additional precision in Y and 4 more bits precision in X. THus we had a YYZXXX format. But then after intense arguments we arrived at the more CLEAN YYYXXXXX format that gave 1 foot everywhere and used identical parsing and processing for both X and Y.

Since YYYXXX could be done with single precision and YYYXXXXX reuired double precision integers we all agreed at the time to simply change the mathematical constant from 380972 to 380926 to allow for this vastly simpler implementation on PIC processors. THere is noting inelligent about this. In fact, it is very elegant.

First of all, you need to understand you are talking two distinct issues. FINDU's protocol, and what is actually sent over the air. I see little reason to mess with FINDU, it's already doing what it's supposed to do, and anyways it's on the internet with no radio ports. The x-no-archive:yes is an accepted standard on the internet already.

In the compressed format there are two unused bits and in the MIC-E format I believe there are also unused bits. Why not just use them for the archive function?

The various RF gateway programs could then expand them in a format that FINDU accepts.

In this way you have a 0% increase in the size of your frame sent over the air.

I think routing issues need to be addressed in the next cut of the APRS protocol, this would address some of the privacy concerns being raised, but more importantly make a real routable protocol. This is having your cake and eating it too. But that's for another discussion.

-Jeff

> feature. I would rather see an ambiguous position which is clearly
> marked as such than seeing purposefully WRONG posits....

This suggestion concerns me. There was a heated discussion regarding the need for position ambiguity on APRSSPEC some time ago, yet I never saw this "use" of it mentioned. More to the point, for those of you who are familiar with robotic navigation, the "ambiguity" itself can express information. That is, how good are your sensors. You use this level of ambiguity to weight your decisions when doing sensor fusion and/or Kalman filtering.

Now I see someone suggesting we use it to hide our true location. This is a entirely separate issue from the FINDU discussion that prompted this suggestion. Its one thing making data readily available to anyone on the internet, its a complete other one purposely putting that data in error on purpose. The problem here is this ambiguity can no longer be modeled, its really random!

Its my opinion, based on my experience in robotic navigation, that this suggested

use
of position ambiguity is a poor idea.... its not even position ambiguity!! Better
to have
a flag to set for no archive, or better yet, work on a real routable protocol then
to yet
again kludge up the protocol.

This is not strictly a academic discussion either, the use of *accurate*
position ambiguity in DF work is important also. Sounds like a oxymoron ("accurate
ambiguity"), but I assure its not. You need to know the accuracy of your sensors
to
be able to use the data properly.

For those of you interested in robotic navigation, here is a interesting text
available
on the internet entitled: Where am I?" -- Systems and Methods for Mobile Robot
Positioning at: <http://www-personal.engin.umich.edu/~johannb/position.htm>
There is a short section at the end on Kalman filters.

Hello ..

I am new to the list and new to APRS. I have a registered copy of Dos APRS. I have this loaded on my home computer and I can also run mobile with a dual port computer and a Garwin gps. I have captured a history map of some of the major streets of the City of Timmins and would like to give a demo of this exciting mode at our general meeting in a few weeks from now. I have used Mapfix40 and this history file to make a map. I can load the map in the window version of APRS but I cannot find a way to insert my Timmins map in the Dos Version. I do not wish to change anything in the Ontario Maps. I just want to be able to display a basic map of our area while a mobile unit circles the surrounding. We will gladly submit maps of our area to be added to the zipped database. We just want a quick fix for the upcoming meeting. Thank you.

So? They have infinite bandwidth. This is HAM radio on a 1200 baud channel. Where every byte counts. putting "x-no-archive" in every packet on the air is a tremendous hog of our precious bandwidth..

>
> In the compressed format there are two unused bits and in the MIC-E format

Because there are thousands of Mic-E's and THD7's and D700's that will never be changed to allow for this...

There is clearly a misunderstanding of APRS position ambiguity below,
which I will try to correct:

On Sat, 29 Apr 2000, Jeff King wrote about Bob's statement that position
ambiguity built into APRS can be used to mask exact positions:

> This suggestion concerns me.... for those of you who are familiar with
> robotic navigation... That is, how good are your sensors....
> Now I see someone suggesting we use it to hide our true location.... a
> separate issue from the FINDU discussion that prompted this suggestion.
> Its my opinion, based on my experience in robotic navigation, that this
> position ambiguity is a poor idea.... its not even position ambiguity!!

"Position ambiguity" in APRS has nothing to do with the Jeff's example...
Position ambiguity in APRS means the same thing as we learn in Highschool
math. And that is that there is a difference between the following
representations of a position: (or any measurable quantity)

38 59.13 N	... is a latitude known to a precision of about 60 feet
38 59.1 N	... is a latitude known to a precision of about 0.1 mile
38 59 N	... is a latitude known to a precision of about 1 mile
38 N	... is a latitude known to a precision of about 60 miles

The DESIGN of APRS included the ability to PRESERVE these POSITION
AMBIGUITYS from the SENDER to the RECEIVER, so that there could be NO
MISSINTERPRETATION of the data on receipt.

But some authors refused to support this fundamental concept in their
implementations of APRS. Thus, some programs will convert, record and
display ALL OF THE ABOVE positions exactly the same at the location of
38 00.00 Whis is just plain wrong.

So, even if someone does not know the hundredths of a minute details of
his positions, even if he only enters it as 3859N and 7629W, those

programs will show him at exactly 3859.00N and 7629.00W with no indication that this position was ambiguous in the first place.

In APRSdos and WinAPRS and any others that support position ambiguity, these station ICONS will look just like anyone else. UNTIL you zoom in below the point where the precision no longer exists. At that point, the ICON is replaced with a CIRCLE with a radius of the ambiguity. Thus you UNMISTAKENLY can see that the station is somewhere within that circle and you are NOT MISLED that he is exactly where his ICOM may fall..

In my opinion, we MUST preserve END-TO-END meaning of positions and that includes the display on RECEIPT of the lack of precision that was INCLUDED by the SENDER. To do otherwise UNDERMINES the integrity of APRS.

de WB4APR, Bob

Now, then, that is why you can use position ambiguity to show what neighborhood you live in, but to remain completely ambiguous as to which house you live in.

Or in the case of the THD7 HT, it allows you to enter a manual position showing that you are visiting in Atlanta, without having to have the GPS plugged in. APRSdos will display any THD7 posit ending in .00/.00 with an ambiguity circle of 1 mile. Thus someone seeing your THD7 at the Atlanta Airport for example, does not waste precious time driving to exactly XXXX.00/XXXX.00 and getting frustrated because he cannot find you there...

Does the D700 work differently than the D7? On the D700, Position ambiguity only affect Latitude.

1 digit: XXXX.X0/XXXXX.XX
2 digit: XXXX.00/XXXXX.XX
3 digit: XXX0.00/XXXXX.XX
4 digit: XX00.00/XXXXX.XX

Just demonstrated this again right now. I believe I've pointed this out before.

The ambiguity with 1 digit, is just about ziltch. And someone who thinks they are being ambiguous with 1 digit, is fooling themselves. At least with 2 digits, you will have a minute of ambiguity. On the D700, this is only in Latitude; you KNOW the Longitude. Call it a bug if you wish, but there are a lot of D700 out there now. Do we tell them, hey, you are not as ambiguous as you think!

How about on your D700? Does it work right?

How about in APRSdos? Do you display the ambiguity correctly?? It should only be a line, not a circle.

At least with "regular" APRS packets, the ambiguity is well defined, with spaces in the Lat/Long. The ambiguity in other Mic-E and compressed is more ambiguous.

Brent

I think this is one that has to be worked out with the author.
Mr. Dimse can probably do anything you want, or he may
take the same position as Kenwood and the others and not
want to modify anything. In any case, there's nothing the
user community can do except use what is programmed in.

Work it out and let us know what all the authors decide.

Yes, there is.

> "Position ambiguity" in APRS has nothing to do with the Jeff's example...

Of course it does, if it has the same thing to do with what we learned in high school chemistry class.

> Position ambiguity in APRS means the same thing as we learn in Highschool
> math.

I think you meant high school chemistry or physics. But it all boiled down to math anyways.

Your 100% correct. Which was my point. The "high school" example had to do with the accuracy of your sensors, in this case a weight balance, pipette, thermometer or whatever. If you were using a number of measurements together, then the known precision of measurement, or ambiguity would be cumulative and would be used in your calculations. While you knew you never got a "exact" measurement, you knew a range that the measurement was in. And it could be accurately modeled. This would be analogous to a range circle in APRS derived from S/A or from the GPS DOP.

Now, the analogy of the way you are suggesting using ambiguity is if your high school chemistry teacher walked around class putting his thumb on the scale while you were taking measurements. Yes, you know the measurement is wrong, but just how wrong we no longer know. The measurements now are useless as the level of ambiguity is no longer repeatable as it was before. Further, the factor introducing the ambiguity is no longer trying to get it as close as possible, but is trying to deceive. This is the fundamental difference you do not understand and two completely different uses of the "_" field.

What your trying to do with "position ambiguity" could be better described as position munging and has nothing to do with the precision of measurement.

Which is fine, just call it what it is. This is more a debate of semantics

anyways.

-Jeff

P.S. Here are some postings made on the APRSSPEC list about 4 months ago. Never a mention from you of position concealing and everyone seemed to understand the high school math/chemistry example then.

In order to encode position ambiguity in the Mic-E format there were available bits in the code space of the LATITUDE bits. Thus, we encoded the 4 levels of ambiguity in the LATITUDE. But again these are BITS that are DEFINED to be AMBIGUITY. They are ambiguity CIRCLES by definition.

The above decodings are incorrect in that they are inserting "0's" in the decoding, again, inserting precision where precision was not intended. The proper decoding of a Mic-E packet with ambiguity should insert spaces in those digit positions.

> How about in APRSdos? Do you display the ambiguity correctly??

Yes, AMBIGUITY is defined at 4 levels of 0.1, 1, 10 and 60 miles. These are circles of ambiguity in both Latitude and Longitude. This is by definition. But it is only necessary to encode this in the LATITUDE information to have it apply. Receiving software should handle it appropriately...

Bob - you did not even address the issue. The D700 does it wrong. APRSdos thus displays it wrong.

No, the D700 does it right and my APRSdos displays it
correctly as an ambiguous circle of radius 1 mile when I select
POS AMBIGUITY of 2 digits on the D700.

Your example below makes no sense since it includes many "00"'s. If position ambiguity is enabled on the D&00 (WHich transmits in Mic-E format), then there are no "00's" in the positions you imply.

OK OK PUT _ in for zeros. The D700 send the REAL Longitude. Even with 4 digit "ambiguity". Decode it yourself. People need to know that only the Latitude is it rounded off only, not the Longitude, and I still say, APRSdos is NOT telling the truth. Decode the data yourself.

End of thread.

Sorry brent, I did address your issue. I agreed with you that the BITS for indicating the 4 LEVELS of ambiguity are encoded ONLY in the LATITUDE bits. I further expalined that POSITION AMBIGUITY is "*defined*" to be a "circle" of ambiguity, even though the BITS used to encode it are only passed in the MIC-E format via the LATITUDE bytes.

APRSdos displays this as an ambiguity circle no matter what the least significant bits of Longityude imply. I hope this helps. OH... I see, yes the LSB of longitude does come through on the positions LIST. I should fix that. It should be masked to the same degree as the latitude. Thanks..

It is more then comes through the position list. IT IS TRANSMITTED. IF you are going to transmit ambiguous positions, DO NOT TRANSMIT THE REAL POSITION. I still hold that the D700 has a bug, in that it transmits the REAL LONGITUDE. It should have been rounded. It is not. Thus, the D700 does NOT have a circle of ambiguity, it has a LINE of ambiguity. And to say otherwise, is misleading to the users.

ONLY if its a display issue. IF the position is going to be passed on, you have to have a consistent, known method of dealing with the data. I've tried making this point before in the past, and its really a certification issue if the data is being munged and passed on. It has to be munged in the exact same manner by every program in the path.

This may not have been what you were referring to, but we do need to make it clear the authors only have latitude to do things as they please with end user applications.
Any transport mechanisms must have a consistent method of handling data.

-Jeff

increase
in bandwidth. In the solution you want to stay with, your looking at adding 56
bits to
the compressed format, a _54%_ increase in its size!

Oh, you say backwards compatibility? Again, you asked a question, and a suggestion
was offered. Just because a old piece of equipment won't support something new, is
no
reason not to make things better. Progress does not imply the old can't work, nor
that
we should not improve what we have. The old can still use the "x-no-ar" format
until
if and when they update.

So, here is what I am suggesting again. In the compressed format, we use the two
unused bits in "COMPRESS TYPE" (T) field. As an example, bit 7 could be set
to indicated "no-archive-x" which would indicate the users desire not to have
their data archived, and bit 6 set could indicate the users desire not to have
their
packets passed to the internet (APRSERVE).

In this way, instead of a 56% increase in the frame size, we get a 0% increase in
frame size.

Now, on to the Kenwood factor. Has it not come to anyones attention that we had
a major radio manufacture release a APRS device without the SPEC even being
finalized? As such, I really *DON'T* see why we are so willing to bend over
backwards
for them. Worst case, they do a firmware upgrade, something us owners of TNC2's
have been doing for years. And with the Kenwood, you don't even have to know how
to pull the chip out of the socket..... its on flash.

And as to the owners of the MIC-E, since that is your company Bob, what would be
required there? Why can it never be changed?

Also, since this question was posted to the APRS-WG, and deals with Kenwood, I
think
something needs to be said. Kenwood has given radios to a number of APRS
authors... no
one has hidden this fact from anyone and this really is a good thing as it both
benefits the author
and gets Kenwoods equipment integrated in display apps. The authors most certainly
deserve it.

But, as some of these same authors site on the APRS-WG and can make decisions
that could benefit or hurt Kenwood (like having to upgrade the firmware), its
really important
these decisions be based on technical merits. I'm not alone in feeling this way,

and would hope
anyone on the WG that has a financial arrangement with Kenwood, be it money or
equipment
donations, might consider reclusing themselves from any votes on the WG that would
affect
Kenwood. I'm *not* saying anyone is doing anything improper, but sometimes
appearances
are important in a standards body. So before anyone blows up at me, please
consider this.

In other words:

1. It is only necessary to specify the ambiguity in the latitude.
2. Any display/reporting program should assume that the same level of ambiguity applies to the longitude as well.
3. Because of #2 above, it doesn't matter whether the longitude is transmitted with or without ambiguity.

Yes. In the past the focus on "ambiguity" was to make sure that all authors "displayed" the ambiguity to the end user so that there could be no misunderstanding in interpretation of a position. We were making no attempt to hide any extraneous precision, because the ambiguity flags were saying the position was ambiguous so it didn't matter.

What Brent has pointed out, in light of the interest in "security", is that APRSdos is capturing the actual data too, so the use of "ambiguity" as a "security" feature is not perfect. I will fix this. All I simply have to do is mask out the digits in the LONGITUDE to match the number of digits of ambiguity in the LATITUDE. But this is done on "receipt" so everyone else will probably have to take a look at how they do it too on receipt.

But this is misleading to the user who thinks they are sending an truly ambiguous position. The D700 is NOT. It transmits the real Longitude. The bits in the Mic-E may have been in the Latitude, but the Longitude could have been rounded before transmission just like the Latitude is rounded. Then the same number of significant digits would have been transmitted for both. But it is not. If this is added tot he Spec, then the whole concept of Ambiguity becomes a farce. If any program represents a station as transmitting an ambiguous position when in fact, part of the position is well known, then this is a misrepresentation of the facts.

I see, we can call ambiguity - DECEPTION ON RECEPTION.

Brent, you are still confusing the issues of POSITION AMBIGUITY with
"SECURITY". Position AMBIGUITY has NOTHING TO DO WITH SECURITY.

Yes, I have confused the issue by bringing up "ambiguity" as a means for
users to provide some measure of ambiguity in their position if they did
not want it desiminated worldwide by FINDU. But your point is well taken
that we should not INFER security with AMBIGUITY.

THE SPEC as written, THE Mic-E protocol, and the Kenwood D700 are all
consistent and work as designed with position ambiguity. Leave it alone.
If there is any reference to "security" in the SPEC, the KENWOOD docs or
the Mic-E docs, then Brent is correct that it is not and should be
corrected.

But your statement that position ambiguity is a "farce" is unfounded.

SECURITY in APRS, I agree, can be considered a "farce" and I hope we do
not imply it anywhere... Thanks for noting this...

And, if you send me your login password, I promise that my client
software won't look at it...

How likely are we to see APRS display programs that provide good

guesses of the location of a station with this feature enabled (based on knowing the longitude and the history of the changes in the latitude)?

I suggest that it makes more sense to admit the limitations of this scheme, rather than to make overly broad claims about the security it provides.

-tjs

True, position ambiguity was not designed as a security measure. My

apologies if I have confused anyone...

Tim, I didn't say anything about security. Neither does the spec say anything about security.

The Spec:

Position Ambiguity Where the exact position is not known, the mm and hh
digits in the latitude
and longitude may be progressively replaced by a V (space) character as the

amount of imprecision increases. For example:
07201.7_W represents longitude to nearest 1/10th of a minute.
07201.___W represents longitude to nearest minute.
0720.___W represents longitude to nearest 10 minutes.
072___.___W represents longitude to nearest degree.

The D700 case: Position is known when you have GPS input. Does Position ambiguity have meaning? How would you interpret Position Ambiguity when you have Live GPS input, particularly now that SA will be discontinued tonight? It is an inconsistent application of the definition. I agree with Jeff King in that we are not reporting our estimate of the error, we are munging the data, and do not know how. Are we rounding or truncating? If we have Live GPS input, the position is not ambiguous. In this case, we can only assume that we are concealing our position.

> The D700 case: Position is known when you have GPS input. Does Position
> ambiguity have meaning?

*** It always has meaning. There are 4 levels as defined above.

> How would you interpret Position Ambiguity when you have Live GPS
> input, particularly now that SA will be discontinued tonight?

*** Exactly as defined above...

> It is an inconsistent application of the definition.

*** Not at all. The 4 levels of position ambiguity are well defined, have unambiguous meaning and are ONLY A MEANS OF COMMUNICATING the 4 levels of ambiguity from the SENDER to the RECEIVER. How these 4 levels are encoded has nothing to do with the definition... Although the example above does use the most obvious (uncompressed) format.

> I agree with Jeff King in that we are not reporting our estimate of the
> error,

*** We Never were. That is not in the definition. I say again, POSITION AMBIGUITY only is a way of communicating the number of digits of precision that the SENDER wants the RECEIVER to use. If the SPEC is not conveying this, then we need to reword the spec. But that has always been the reason, purpose, definition, and implementation of position Ambiguity.

> we are munging the data, and do not know how.

*** I don't see ANY munged data. Position ambiguity CONVEYS to the receiver the number of DIGITS of precision the SENDER wants the RECEIVER to use. It is really very simple...

> Are we rounding or truncating?

*** Doesn't matter. What "position ambiguity" conveys is the number of digits of precision. It does not address the remaining digits. That is up to the sender or initiator of the data to enter what he wants to convey.

> If we have Live GPS input, the position is not ambiguous.

*** It doesn't matter. "Position ambiguity" in APRS has NOTHING TO DO WITH THE ACCURACY nor the PRECISION of the original position. It has ONLY to do with the number of digits that the SENDER intends for the RECEIVER to use...

> In this case, we can only assume that we are concealing our position.

*** Assume anything you want. It is not germane. The SENDER indicates via POSITION AMBIGUITY the number of digits he wants the RECEIVER to use

in his display of position. His reason for doing so does not matter.

*** Due to the apparent misunderstanding of Position Ambiguity, I would suggest a change to the spec from:

Position Ambiguity where the exact position is not known...

to

Position Ambiguity allows the originator of position data to convey to the receiver of that data the number of digits of precision to use in the display of his position. In the uncompressed format, this is accomplished by.....

... In the Mic-E this is accomplished by encoding using available bits in the LATITUDE field.

I actually was agreeing with what Bob has posted on this very SIG a few months ago. Posted some links to it also earlier in which he agreed/didn't object to it then.

Yes, that's its purpose this week. Understand Brent? ;-(

Rounding or truncating needs to be in the SPEC. It DOES matter if you want a consistent user space, and MUST be defined if the data is passed on.

> ...

Well, at least SA was turned off today! ;-(

I am probably confused as to the precise (if you will excuse the pun)
motivation for position ambiguity.

And from the TM-D700A Instruction Manual (Specialized Communications):

Programming Position Ambiguity

There may be cases where you do not know or do not want to report your precise locations. For position data, you can select the number of digits not to be included in your packets. ...

I suggest that the APRS protocol spec note the limitations of position ambiguity as a security measure (since it has been touted as a security facility repeatedly and for some time).

Well, you already know my feelings on letting Kenwood influence APRS development, but do note they say "where you do not know OR do not want to report your precise locations". Two distinct uses of position ambiguity, the first to convey the level of precision (our much touted high school example) and the other as a security measure.

> I suggest that the APRS protocol spec note the limitations of position
> ambiguity as a security measure (since it has been touted as a security
> facility repeatedly and for some time).

But its also been touted as a means to convey level of precision, see this posting from Bob from 1998 which is pre-WG:

<http://www.tapr.org/tapr/list-archive/aprssid/9810/msg00985.html>

This use of position ambiguity appears consistent with what the WG adopted.

The spec says:

>Position Ambiguity A reduction in the accuracy of APRS position information
>(implemented by replacing low-order lat/long digits with spaces). Used when the
>exact position is not known.

Implies the user (or sensor) gives their best guess as to their location, then that level of precision is carried in the APRS payload.

I repeat again. There is value in conveying a ACCURATE level of ambiguity. One need only look at the DF scenario to understand this and any other number of future applications of APRS in the communications field. While I understand that someone could use ambiguity as a means to purposely mask their position, I'm not comfortable with that being advocated in the spec (its not presently). There are much better long term means to do this, such as adoption of routing in the spec as well as flags the users can set to restrict the propagation of their posits.

-Jeff

P.S. Does anyone know if position ambiguity can be represented in the compressed format? As it starts with a numeric, it doesn't appear to me it can support position ambiguity. Now, it does have a GPS lock flag I note.

Thought it was time for a reminder.

The current SPEC is to define the protocol AS IS on the air RIGHT NOW.

I agree the position ambiguity leaves some room for improvement, as are many

other things.

The APRS WG should put on their list of things to address in the NEXT version of the protocol.

Neil Johnson

I'm confused, exactly who is suggesting the spec be changed? With regards to the definition of Position Ambiguity, looked fine to me as it was in the SPEC.

Or where you talking about Kenwood here?

-Jeff

I haven't been privy to the secret discussions of the APRS Working Group, but there have been some hints that this isn't entirely the case. I believe that there have been some cases where the protocol has been modified slightly in the process of developing the spec. In one or more of these instances different software implemented the protocol differently (which makes it difficult to say with precision what the on-the-air protocol really is).

I also believe that several deprecated protocol features are not contained in the spec, so a liberal implementation will have to accept protocol features beyond what are in the spec.

=====
APRS WORKING GROUP
APRS PROTOCOL REFERENCE
THIRD PUBLIC DRAFT
=====

The APRS Working Group has now published the third (and hopefully final) public draft of the APRS Protocol Reference. It is available on the TAPR website, at <http://www.tapr.org/tapr/html/Faprswg.html>.

This latest draft incorporates *hundreds* of items of feedback received since the previous draft published last December, and has now grown to 115 pages.

Several sections have been considerably expanded and clarified. In particular, the chapters on Mic-E, Weather Reports and APRS Symbols have been substantially rewritten.

The Working Group invites feedback on the specification, although due to the extensive public comments that we have already received on prior drafts, we will not have a formal comment period as defined in the WG charter; what we ask for now are additional eyes to ensure that we haven't inadvertently introduced new errors to this draft. Comments should be addressed to the TAPR "aprsspec" mailing list. Details of how to join the list are given on page 2 of the document.

The cutoff date for feedback is midnight local time on Monday 15 May.

Then, depending on the amount of feedback received, the Working Group hopes to publish the Final Approved version of the specification a few weeks later.

John Ackermann, N8UR
Administrative Chair, APRS Working Group

Congrats on getting the next revision to the specification on the street!

One question I have had since recently joining the APRS legions has to do with the PHG(D) data extension. There is no discussion of where in the system the power figure is measured. The logical choices are at the transmitter antenna jack or at the antenna input connector. Maybe I'm too much the novice here, but it seems like a brief explanation is indicated to discuss where the "P" in PHG is measured/calculated. It seems logical to

assume that the figure is taken at the input to the antenna in order to facilitate a rough ERP estimate. Depending on the loss in the feedline I realize the delta between the two points of measurement may be lost in the calculation algorithms.

Hi All-

First of all I would like to express my thanks for all the work that went into the Draft Protocol.

I have a couple of questions concerning Hurricane format. The Draft has a 5 character field for the minimum central pressure- expressed in tenths of a millibar. The hurricane center reports only in full millibars, so the final digit would always be zero. Also presently the field is three digits- with pressures above 999 having the beginning "one" truncated. If the

change is going to be 5 digits I need to know if present software can handle it. (At this writing we are 27 days from Atlantic hurricane season, 12 days from pacific.)

As for as course and speed- the spec is for knots for a forward speed for all objects (I believe). However the D700a has a "m" after the speed for an object, which I assume is for "MPH". Things are OK if this is a nautical mile per hour. At present I am reporting tornadoes and thunderstorms in MPH and Hurricanes in knots, and I would like to get off the fence. One solution is to report in knots and try to get the word out to D700a users there is a display bug. Which way should I go?

Thanks again for the hard work.

Your analysis is correct. It is not an exact science... Power getting to the antenna...

Good point Henk. But I would modify your suggestion as follows:

- 1) If there is a mix of SSID routing and VIA paths, then the VIA path shall be used first. And each HOP is used up in the usual fashion.
- 2) SSID routing should only apply when:
 - a) There is no additional path *or*
 - b) All additional hops have been used up.

This solves the ambiguity you noted, but is the least restrictive. It allows for future versatility. For example, I am one hop away from an SSID network (say, in my basement with an HT), this would let me use APRS-4,RELAY and be able to get into the SSID system.

> Another remark on the new specification:
>
> Maybe it should be prohibited that if the destination SSID of an APRS packet is not 0 then there shall be no digipeaters in the VIA list, or that digipeating on destination SSID only works without any digis in the VIA list. Otherwise you will get a mixup of old and new digipeater implementations. Old ones that just use the VIA list regardless of destination SSID and new ones that act on the destination SSID. Since the destination SSID digipeating is introduced to keep the packet small there is also no point in having a VIA list. My proposal:

For Hurrican PRESSURE, we are waiting for comments from Mark. He was out of town during the last round of comments, and I confused myself and everyone else by "thinking" of the PRESSURE in the normal WX report (5 digits) and not the Hurricane format (which I do NOT parse I just display it as written).

So, Dale, and Mark (and anyone else with an opinion) settle it. I'll go with whatever you want.

It is nice to see the added explanation of data transfer units and display units and also the collection of required conversion factors into a single table (from scattered around the glossary in the 1.0.1g version).

However, I would like to emphasise the importance of doing these conversions properly. Assuming the data is generated in some unspecified unit A and in order to use the on-the-air unit B, the value must be multiplied with a factor x . If we want to display the value at the other end in unit A, the on-the-air value must be multiplied by $1/x$. However, if too small numeric precision is used to express the $1/x$ factor, the original value will not be represented.

To exaggerate, assume that the on-the-air unit is six times smaller than the original measurement, thus $x=6$. If the source will produce a measurement of 100, the on the air value will be 600. Assuming $1/x$ or $1/6$ is represented with only two decimals, we would get 0.17 and multiplying this with the on air value, will give 102, which is clearly different from the original value. If the value is rebroadcasted, the error will cumulate.

This is just what happens with some values in the conversion table. For instance one foot is exactly 0.30480000... meters by definition, but the constant for $1/x$ is given as 3.2808 with only five significant digits, while even the single precision IEEE floating point system (used in e.g. x86 and 68k series processors) give 6-7 digits and double precision 14-15 digits.

I have recalculated the conversion factor values to at least 14 significant digits (use fixed pitch font for better readability):

> Units Conversion Table

>Multiply	by	to get
>feet	0.3048	meters

(this is by definition)

```
>meters      3.2808      feet
              3.2808398950131
```

```
>miles      1.609344      km
>km         0.6214      miles
              0.62137119223733
```

```
>miles      0.8689762 nautical miles
              0.86897624190065
>nautical miles 1.1507794 miles
              1.15077944802354
```

```
>miles per hour (mph) 0.8689762 knots
                      0.86897624190065
>knots 1.1507794 miles per hour (mph)
              1.15077944802354
```

```
>knots 0.514440 meters / second
>meters / second 1.9438446 knots
              1.94384449244061
```

(note that the last digit in the original value was incorrect)

```
>miles per hour (mph) 0.44704 meters / second
>meters / second 2.2369362 miles per hour (mph)
              2.2369362920544
```

Some of those values are still approximations after 14 digits and since multiplying by $1/x$ is the same as dividing by x , it would be better to reformat the table slightly and only use exact values by either multiplying with or dividing by the exact value. In some cases both multiplication and division had to be used

Units Conversion Table

Convert from ! multiply by ! divide by ! to get

feet	!	0.3048	!		!	meters
meters	!		!	0.3048	!	feet

miles	!	1.609344	!		!	km
km	!		!	1.609344	!	miles

miles	!	1.609344	!	1.852	!	nautical miles
nautical miles	!	1.852	!	1.609344	!	miles

(mph)	!	1.609344	!	1.852	!	knots
-------	---	----------	---	-------	---	-------

knots ! 1.852 ! 1.609344 ! miles per hour (mph)

(knots ! 0.514440 ! ! meters / second)

(m/s ! ! 0.51444... ! knots)

or better yet

knots ! 1852 ! 3600 ! m/s
m/s ! 3600 ! 1852 ! knots

(mph) ! 0.44704 ! ! m/s
m/s ! ! 0.44704 ! mph

Examples:

5 ft = 5 * 0.3048 = 1.524 m or rounded to 1.5 m

12.5 km = 12.5 / 1.609344 or about 7.77 miles.

7.45 kt = 7.45 * 1.852 / 1.609344 or about 8.57 mph

In order to avoid unnecessary conversion errors, it is important that all stations use the same conversion constants and formulas. By including these into the specification, the risk is greatly reduced that some implementor decides to make some shortcuts that may cause conversion errors.

The ILOVEYOU virus hit us hard at work and as a result, very little email has gone in or out of my workplace. If you sent SIG-administrator-related mail to my work email address (stan_horzepa@adc.com) early Thursday morning or later, I likely did not get it and likely won't get it. So, please resend it to wallou@tappr.org.

And, for the time being, only send SIG administrator mail to the email address of wallou@tappr.org.

Thanks for your cooperation,

Stan Horzepa, WA1LOU, SIG administrator

=====
ANNOUNCING "APRSDEC"
THE FULL APRS DECODER PROGRAM
by Ian Wade, G3NRW
6 May 2000
=====

While working on the APRS Protocol Specification, I found it useful to write an APRS Decoder Program (APRSDEC) to verify the details of the protocol.

APRSDEC parses APRS packets in IGate output format, and produces a full decode of all elements of each packet. This will be particularly useful for APRS developers/testers, and also for people who need/want to know more about the protocol, or who want to check out their own packet formats.

Among the more obscure formats, APRSDEC fully understands Mic-E, compressed positions and area objects (circles, triangles etc).

Here is an example of APRSDEC output:

~~~~~  
~~~~~  
APRSDEC. APRS Packet Decoder.
Version 1.0.1b (5 May 2000)
by Ian Wade, G3NRW (g3nrw@arrl.net)

Runtime = 06-May-2000 16:13:21
Input file = examples.log
Output file = examples.out

NOTE: If this report contains anything that you think is incorrect,
please email it to g3nrw@arrl.net for investigation. Thank you.

+++++ END OF INPUT FILE +++++

~~~~~  
~~~~~

With a few unimportant exceptions, APRSDEC understands all of the APRS features included

in the Protocol Specification. As an extreme example, look at Record #7 above.
This draws
a line object with a 10-mile corridor either side, and is carefully contrived to
cross
both the Greenwich Meridian and the Equator -- the offset posit shows the position
of the
end of the line, in the opposite latitude and longitude hemispheres.

APRSDEC even recognizes Kenwood TM-D700 radios, and corrects the posit to be a
current
posit rather than an *old* posit. Position ambiguity (Mic-E and uncompressed lat/
long) is
also handled correctly.

APRSDEC includes extensive error reporting, showing for example when a parameter
is out of
range, or in is the wrong format, or (in the case of NMEA sentences) where there
is a bad
checksum.

APRSDEC is now available at <http://www.netro.co.uk/aprs.htm>

This is the first publicly released version, and I would welcome any feedback,
especially
if you find any errors.

Hello group -

In the recent discussion about position ambiguity, Bob stated that DosAPRS shows a "circle of ambiguity" below certain scale factors.

However, the ambiguity is given as a certian latitude and longitude (the latter directly or inferred, depending on the encoding device).

with all due respect, displaying this ambiguity as a circle is wrong. It is a rectangle!

>
>with all due respect, displaying this ambiguity as a circle is wrong. It is
>a rectangle!

Agreed. For example, for the posit 1234. N/12345. W-, the location is only known to the nearest minute, so the rectangle looks like this:

12deg 34.99min N		12deg 34.99min N
123deg 45.99min W	+-----+	123deg 45.00min W

One observation: APRS uses Degrees/Minutes for Lat/Long. The decoder reports Degrees/Minutes/Seconds. I should clarify, APRS uses Degrees/Minutes for most packets reporting position. Mic-E is also encoded from Degrees/Minutes. The ? APRS? range query uses Decimal Degrees. NMEA is also a form of Degrees/Minutes. I would suggest reporting position in your decoder as Degrees/Minutes, in place of Degrees/Minutes/Seconds to be consistent with APRS format. Brent

OK, I understand that. In fact, others have asked for temperatures in Celsius, speeds in km/hour, meters/sec etc. So in the next release there will be a .INI file where you can set up your own preferences.

Ian, this battle has been raging from day one. And I think we even got it
into the spec that the "standard" format for APRS is DEGS and MINUTES.

Yes, you can convert and display in anything you want, but we prefer that
such displays make it clear what the APRS standard is so that when we are
talking VOICE we have some degree of consistency. I am amazed at what I
hear on the air. So many folks don't know the difference between seconds
and decimal minutes and use them interchangeably. To avoid this tower of
babble we prefer to entrench in to the APRS community, only one "standard"
method. They can convert as needed... but we need a "common" approach
throughout APRSdom...

Bob

Agreed Bob. My approach in future with APRSDEC will be to ALWAYS report the output in APRS standard units (with no means of turning that off), PLUS an optional conversion in parentheses (as I have already done in converting knots to mph, for example). In fact, in the current version, everything except lat/long *is* reported in APRS standard units.

Hello everyone -

I am concerned about the statement at the bottom of Page 11 of 1.0.1m
on "Map Views and Range Scale".

First, let me provide the definitions >>I<< use:

Map - the visual presentation of a geographical data base through which the the user can navigate without manually requesting the loading of a new map.

View - that portion of a map which is visible on a computer screen at any instant, without any manipulation. The view may encompass an entire map, or it may encompass much less than an entire map.

Here is an example. In WinAPRS or MacAPRS, you get a U.S. map and some regional maps. If you want to view anything in any detail, you need to go to a menu and select another "map" (say, Washington). Within any map, you can shift the view to see a region of the map. That region can be as large as the whole map or it can be some smaller part as the result of "zooming in". But, there is still a point beyond which, if you want more detail, you have to load yet another map. This is the distinction I make between Map & View.

=====

The quote:

APRS is a tactical geographical system, and users need to be able to relate map views in a non-ambiguous way. Thus all map displays should have a meaningful legend to convey the scale of the map view to the user.

Thus when communicating about such views, three parameters are required:
the latitude and longitude of the map center and the Range Scale.

In this context, the Range Scale is the approximate range (in nautical miles, miles or km) from the center of the map to the top or bottom. This convention gives all software users a common basis for describing tactical map views (at whatever Range Scale is in use).

=====

(end of quote)

Suppose that you are using APRS+SA. There, the map covers the entire surface of the earth. You can move seamlessly to any place on the earth without having to load a single "map". For the SA map, the center of the map is 0000.00/00000.00 and the Range Scale is 6220 miles (approx distance from equator to either pole). I find no use for this "info" at all.

Suppose that the user has a very detailed map of the (contiguous) U.S. and the center is somewhere around Nebraska. And, suppose that the user has zoomed in to view the Seattle area. Pardon me, but the location of the center of the map and the "Range Scale" don't matter one iota. What does the user care while viewing a boat on the Puget Sound that the

"center" of the map is out there in "no-human's land".

Suppose that we substitute the term "view" for the term "map" in the quoted text. It still makes no sense. Here is an example:

I can have a view which is the full width of my monitor screen but with a very small height because I am watching vehicles along I-84 in the western U.S. while monitoring my local APRS traffic (in other non-map) windows. What information does this "Range Scale" provide? It may be only 50 miles while having an east-west extent of 500 miles or more.

For that matter, I just might even have multiple map windows (with several open and visible at the same time).

But, then, what DOES matter? To my mind, the only thing that does matter is that stations in an event be able to view locations which are of shared importance. If a user can readily shift the location of a view to "see" a specified geographical location or a specified symbol (or symbols), can determine the geographical location of a point within the current view, and determine the distance between two points in the view, then that is sufficient.

It seems to me that this statement is a hang-up on the idea of military tactical map display. I argue that its usefulness is nearly zero for real-world ham application of APRS. If Bob wants to develop commercial applications of APRS which can be sold to the military, that is one thing. But to shackle us with that requirement makes little or no sense at all.

Thanks for putting up with my rant!

Jim, KA7EHK

On Wed, 10 May 2000, James Wagner defined VIEW:

> View - that portion of a map which is visible on a computer screen

Then he noted:

> =====
> APRS is a tactical geographical system, and users need to be able to
> relate map views in a non-ambiguous way. Thus all map displays should
> have a meaningful legend to convey the scale of the map view to the
> user.
>
> Thus when communicating about such views, three parameters are
> required: the LAT/LONG of the map center and the Range Scale.
>
> In this context, the Range Scale is the approximate range (in nautical
> miles, miles or km) from the center of the map to the top or bottom.
> This convention gives all software users a common basis for describing
> tactical map views (at whatever Range Scale is in use).
> =====

He then correctly argues that the center of the "MAP" is meaningless. He is right. Lets change the above paragraph from "map" to "view". Clearly "view" was intended.

> Suppose that we substitute the term "view" for the term "map" in the
> quoted text. It still makes no sense. Here is an example:
>
> I can have a view which is the full width of my monitor screen but with
> a very small height because I am watching vehicles along I-84 in the
> western U.S. while monitoring my local APRS traffic (in other non-map)
> windows. What information does this "Range Scale" provide? It may be
> only 50 miles while having an east-west extent of 500 miles or more.

Yes, but your range scale is then 50 miles. This UNAMBIGUOUSLY will assure that if I am ALSO looking at the same CENTER COORDINATES and RANGE SCALE of 50 miles that I will also see everything that you are seeing in that same area.

> For that matter, I just might even have multiple map windows (with
> several open and visible at the same time).

Fine. Each "view" still has center coordinates and a range scale.

> It seems to me that this statement is a hang-up on the idea of military
> tactical map display. I argue that its usefulness is nearly zero for
> real-world ham application of APRS.
> Jim, KA7EHK

If you have an alternate way to communicate "view" scales unambiguously to all users, across all platforms and software types, then please share it with us. Thanks

What is the lowest central pressure ever likely to be reached in a severe tropical storm/tornado/hurricane etc? I have no idea. 800 mbar? 700? 600? Lower yet?

Is there any point in expressing it to the nearest 0.1 mbar?

Earlier, I posted a "rant" about Map Center and Range Scale. I offered the the example of a view encompassing a large portion of I-80 in the West. It shows perhaps 100mi N/S and 1000mi E/W.

Now, someone else can have the same range scale (50 mi) and the same center, but have an E-W extent of only 200 mi. Clearly, the two views do not show the same information!

Bob responded:

>
>Yes, but your range scale is then 50 miles. This UNAMBIGUOUSLY will
>assure that if I am ALSO looking at the same CENTER COORDINATES and RANGE
>SCALE of 50 miles that I will also see everything that you are seeing in
>that same area.
>

Yes, but having the same Center Coord and Range Scale does not mean that you and I can see the same thing.

Bob further responded:

>
>If you have an alternate way to comunicate "view" cales unambiguously to
>all users, across all platforms and software types, then please share
>it with us. Thanks
>
>Bob, wb4apr
>
>

There simply is NOT enough information.

One of the following will work:

(1) Center Coord + N/S extent PLUS E/W extent

or

(2) N. Boundary, S Boundary, E. Boundary, and West Boundary

or

(3) anything else which is translatable into a specification of the four edges of the view.

Sincerely,

Jim Wagner

Hi All-

From Chris Landsea;s Hurricane FAQ-
Typhoon Tip in the Northwest Pacific Ocean on 12 October 1979 was measured to have a central pressure of 870 mb and estimated surface sustained winds of 85 m/s (165 kt, 190 mph).

No reason to have tenths of millibars- it is not reported that way- for programming - and using 3 digits-
below 500 needs to have a "1" added to the beginning for display- above 500 to 999 - just display1

For example 010 would be displayed "1010"
957 would be displayed "957"

No you are confusing the term range scale. You may be looking at a LONG flat horizontal view and I may be looking at a TALL skinny view, but there is absolutely no ambiguity possible in our definition of range scale. That is "the largest circle that will fit in the view." That was always my definition. As written in the spec, we used the distance from the center of the view to the top or bottom, but in the examples you have raised, I think it would be better if we went back to this fundamental definition.

Something like:

"Range Scale is the radius of the largest circle that will "conviently" fit on the map view"... This way you may have the long flat and the tall skinny views if you like...

Yes, that would be absolutely correct, but absurd to use in voice communications. I am trying to define a consistent but "brief" means for human communication. By voice I say "go to X/Y at the Z range scale." What could be simpler.

As long as that is the standard, then I do not object to the option of saying "I am viewing X/Y with a N/S range scale of A and an east west range scale of B". This is perfectly acceptable... As long as the single value is the understandable default.

Group -

Here is my point:

I have a view that has a N/S extent of 100 miles and an E/W extent of 1000 miles. The Range Scale is 50 miles. The center is Cheyenne, WYO.

My buddy Fred has a view (with the same center) with a N/S extent of 100 miles and E/W extent of 100 miles. His Range Scale is 50 miles.

I call up Fred on the local voice repeater and say "Freddy, o'l buddy, you see that truck symbol out there, east of Lincoln, Nebraska?"

He can't see it on his view because it does not have the same E/W extent as mine. Range Scale is simply not a SUFFICIENT view descriptor.

Jim Wagner,
KA7EHK

PERFECT EXAMPLE! Of how important the concept of CENTER and RANGE are!

- 1) You didnt communicate CENTER to Freddy.
- 2) You didnt communicate RANGE.
- 3) Your example shows exactly how useless on-air discussion

of map views are without these two parameters...

Thanks, I hope you now see how important CENTER and RANGE are to any meaningful communications regarding map views...

Bob

My example omitted one thing, only. It DID say that the two views have the same center and range. {It was by pre-arrangement}.

The example was exactly to show that Center and Range are INSUFFICIENT.

The two views, one 100mi by 1000 mi and the other 100mi by 100 mi. They have exactly the same center and the same range. One sees a drastically different picture of the world than the other.

Another number is needed. You are trying to specify a "rectangular" region on the surface of the globe. You can specify the four corners, the four

edges, or the center plus "range" distances in an orthogonal coordinate system (normally aligned with the lat/lon coordinate system).

Very simply, any thing else is not sufficient.

It is not adequate.

It is incomplete.

Its NOT GOOD ENOUGH!

Then why did you choose to talk about a Truck that was 500 miles away
and 450 miles outside of that "range"? In this case, the center and
range are not insufficient. In this case they were just plain wrong.

> The example was exactly to show that Center and Range are INSUFFICIENT.

I disagree. Within the "SAME RANGE". Both see EXACTLY THE SAME VIEW.

> Another number is needed. You are trying to specify a "rectangular" region
> on the surface of the globe. You can specify the four corners, the four
> edges, or the center plus "range" distances in an orthogonal coordinate
> system (normally aligned with the lat/lon coordinate system).

No I am not trying to define a "rectangular region" Look at the
definition (or the way the definition should be written). RANGE is the
approximate size of the largest circle that will fit within the view.
"Range" of a map view is measured from the center outward.

If you want to extend this, then range can easily refer to rectangles if
you want by refereing to a N/S "range" and and East/West "range" if you
like. But a single "range" is the lowest common denominator
that unambiguously gives two separate operators the necessary
information to describe the same field of interest.

RADIO waves go out radially in all directions. They dont go out in boxes.
Radio waves have "range". Distance has "range". Grandma's house is 75
miles away. It is not 50 miles east and 25 miles north.

This definition of Range Scale does not appear in the document.
Anywhere.

With digipeating, it makes little sense to me to confine "range" to some circle defined by direct RF coverage. We commonly see stations (here in Western Oregon) that are 400 miles or more distant (without use of gateway).

I will entertain the change as noted below:

APRS is a tactical geographical system, and users need to be able to
relate map view in a non-ambiguous way. Thus all map displays should
have a meaningful legend to convey the scale of the map view to the
user.

Thus when communicating about such views, three parameters are
required:
the latitude and longitude of the map center and the Range Scale.

In this context, the Range Scale is the approximate range (in nautical
miles, miles or km) from the center of the map to the top or bottom.
This convention gives all software users a common basis for describing
tactical map views (at whatever Range Scale is in use).

=====

CHANGE "map" to "view" and change "top or bottom" to "nearest edges".

>Its NOT GOOD ENOUGH!

Here is another approach. Consider these two windows, each with exactly the same geographical center and the same range scale. (The range circles are represented by hexagons, as I can't draw circles here). The "C" represents a car, and the "T" represents a truck.

....Bob's Window....

.....Jim's Window.....

Bob and Jim have agreed on the same geographical center and range circle

radius.

Bob says: "Can you see the car, Jim?" Jim says: "Yup"

Jim says: "Can you see the truck, Bob?" Bob says: "Nope!"

In other words, Bob's definition of using "map views" in a non-ambiguous way is only guaranteed to work WITHIN THE RANGE CIRCLE.

~~~~~  
[Does Bob's definition stem from the military perhaps, where screen sizes (and hence views) used to be fixed in an approx 4:3 aspect ratio? This is OK in a full-screen DOS environment, but totally inappropriate in Windows].

A way round this is to change the definition in the spec:

1. Remove completely the concept of "map view". (The "map view" depends on the user's whim in selecting an area to look at -- users can select windows of any size and shape, and can pan/zoom at will within a window).
2. Replace "map view" with "Reference View". The "Reference View" is the area within a range circle of radius R centered at lat/long Y/X.

Users will agree the "Reference View" with each other. They will then have a non-ambiguous understanding of the area they are talking about. (The fact that Jim can also see a truck in his window is irrelevant. If Jim wants Bob to see the truck, he has to increase or re-center his range circle to include the truck, then tell Bob the new "Reference View").

Note that the "Reference View" is the area within the range circle ON THE GROUND, not in the display window.

~~~~~  
Depending on how the user pans and zooms:

1. The "Reference View" need not be centered in the window.
2. The "Reference View" may not even be visible in the window at all.
3. The whole of the "Reference View" may be displayed in the window.
4. Only part of the "Reference View" may be displayed in the window.
5. The boundary of the "Reference View" may or may not touch the upper/lower edge of the window.

The Y/X and R values define the "Reference View" completely and unambiguously.

The "Reference View" is not in any way related to the display window/screen

geometry-- if the range circle happens to touch the top/bottom edges of the window, that is just a coincidence.

Ian,

A method I use to display a view of a map described as Lat, Lon,
and Radius is to create a rectangle :

Upper Left corner = Lon - RadiusInDegrees, Lat - RadiusInDegrees.
Lower right corner = Lon + RadiusInDegrees , Lat + RadiusInDegrees.

This provides rectangle that will contain the ellipse described by
Lat, Lon, and Radius.

As you pointed out, the aspect ratio of the rectangle (ellipse) may
differ from the aspect ratio of the currently displayed map window.
If so, the map view must be scaled to contain the ellipse. It is likely
that the ellipse will touch either the top and bottom, or the sides
but not both. The resulting map view should, at a minimum
contain all objects described by Lat, Lon, radius.

IMO, Lat, Lon, Radius is sufficient information to create the view
intended and no other information is required.

Ran across a freeware program that simulates a NEMA data stream, and thought it might be of use to some on the list. You can see it at:

<http://www.sailsoft.nl/software2.htm>

I don't think that I am getting through!

The spec says (and Bob seems to concur) the following:

APRS is a tactical geographical system, and users need to be able to relate map view in a non-ambiguous way. Thus all map displays should have a meaningful legend to convey the scale of the map view to the user.

When one user has a view that encompasses 100mi X 800 mi and another has a view that encompasses 100mi X 100mi, they have, by the definition Bob has been presenting, the same Range.

I assert that this is the very opposite of a "non-ambiguous way". Even the change to "nearest edges" does not solve it. Consider one user with a view 100mi (N/S) X 800mi (E/W) and the second with a view 800mi N/S and 100mi E/W. These users have the same Range but see vastly different information.

Why the hangup with a "circle"? We are not dealing with artillery or rockets or torpedos. We are not confining ourselves to non-digipeated signals. It takes only one more number conveyed to provide a full, unambiguous description. Why is this a problem?

Why not do what the statement asserts: "able to relate map views in an unambiguous way". Anything other than four coordinates of your choice simply does not give an unambiguous description of a view. And any four, in an orthogonal coordinate system, are translatable to any other four. Lets face up to the world of real-world geometry and quit trying to cut corners. Why is one more number such a problem?

I can see only two ways for Bob's three-quantity description to be sufficient:

(1) There is a region marked out on the view which says "this is the region visible by others who have the same Range you have."

(2) Force views to be (geographically) "square".

I, as a user and programmer, will not accept the second. The first is nearly trivial but is a pain in the rear to have to do when its not necessary and when (almost) nobody else does it.

Very sincerely,
Jim Wagner, KA7EHK

I like Ian's suggestion of a "Reference View".

However, I am still really puzzled about this business of trying to save
one coordinate which would completely specify a rectangular view of any
aspect ratio.

Agreed, Jim. I think the basic problem here is distinguishing between a
display view (i.e. what is visible in a window on the screen) and the
on-the-ground view.

Specifying a display view is meaningless. Anybody can choose any
size/shape for their window, and can pan/zoom in that window to any
extent. What is visible in that view is totally at the whim of the user,
can change from instant to instant, and cannot be communicated in any
useful way to any other user.

Specifying an on-the-ground view is simple, unique and unambiguous: e.g.
Y/X and R. Everyone is referring to the same piece of ground. How they
choose to display that piece of ground is an entirely separate matter,
but it's still the same piece of ground. The on-the-ground view has

nothing to do with whether a circle (or rectangle) touches the top/bottom of the window.

>

Specifying a rectangular on-the-ground view with 4 parameters is not a fundamental problem; e.g. center Y/X, Y offset from the center (equivalent to the radius of Bob's range circle) and X offset from the center. The only difficulty today is that the spec describes the *current* APRS state, and current APRS software (as far as I know) does not support a 4-parameter definition of "map view".

>I can see only two ways for Bob's three-quantity description to be sufficient:
>
>(1) There is a region marked out on the view which says "this is the region

i.e. the region INSIDE the range CIRCLE.

>
>(2) Force views to be (geographically) "square".

I don't think anyone ever intended that.

To re-focus:

All of this discussion relates to a section in the "APRS Design Philosophy" chapter of the specification. This is not the place for specifics on how a "map view" is defined or represented.

The only thing that is important in this section is the idea of common agreement between users on defining a particular piece of ground. How that piece is defined is an *operational* issue. Whether it is a circle, rectangle, ellipse or polygon is outside the scope of the on-the-air APRS spec -- nothing is transmitted on-air that defines the piece of ground.

Accordingly, I propose the following as a replacement for the existing "Map Views and Range Scale" section:

~~~~~  
Viewing Geographical Areas of Common Interest  
=====

APRS is a tactical geographical system. To maximize its operational effectiveness, users need to have an unambiguous understanding of geographical areas of common interest when communicating with each other.

This means that users need to be able to specify the extent of such areas (for example, inside a circle of particular radius centered on a particular lat/long position, or inside a rectangle with particular corner lat/long coordinates). Once a user has specified a geographical extent, other users viewing the same extent can be sure they are looking at exactly the same geographical area.

The method of defining geographical extents is an operational issue, outside the scope of this APRS Protocol Reference -- nothing related to extents is transmitted on-air. However, it is expected that APRS user software will provide easy-to-use tools for defining and viewing extents, and that operational procedures for communicating those extents to other users will be put in place.

~~~~~  
How does that look?

In article <LYR14779-83725-2000.05.14-00.34.20--Ian.Wade@care4free.net@lists.tapr.org>, Jim Wagner <wagnerj@proaxis.com> writes
>Group -
>
>I like Ian's suggestion of a "Reference View".
>

Except that I now want to withdraw that suggestion, for two reasons:

1. Looking back through Jim's earlier messages in this discussion, I am now more firmly of the view <groan> that the word "view" should only apply to what you see in a display window -- "this is my view of this piece of ground, and I can pan/zoom/change the window any way I want to get a completely different view of the same piece of ground". In other words, the word "view" is irrelevant to this discussion (and therefore

irrelevant to the spec).

2. By suggesting the specific term "Reference View", I am imposing a definition on something that is not directly to do with this specification, but will possibly be defined in *other* specifications. I don't have the right to do that.

In another message today I proposed new text which includes the words "geographical extent". I think that overcomes the 2 objections above.

Now I'd like to venture:

Viewing Geographical Areas of Common Interest

=====

APRS is a tactical geographical system. To maximize its operational effectiveness, users need to have an unambiguous understanding of geographical areas of common interest when communicating with each other.

This means that users need to be able to specify the extent of such areas. For example, the area inside a circle of particular radius centered on a particular lat/long position could be specified. When communicating about this circular area's extent, three parameters would be required:

- 1 the latitude of the center of the area
- 2 the longitude of the center of the area
- 3 the horizontal distance from the center to the perimeter of the circle.

Once a user has specified a geographical extent, other users viewing the same extent can be sure they are looking at exactly the same geographical area.

The method of defining geographical extents is an operational issue, outside the scope of this APRS Protocol Reference -- nothing related to extents is transmitted on-air. However, it is expected that APRS user software will provide easy-to-use tools for defining and viewing extents, and that operational procedures for communicating those extents to other users will be put in place.

Several days ago, some brave soul asked on this list if an APRS sound board program compatible with APRS existed. If anybody answered him I missed it. Sound board programs now read RTTY, PSK31, PACTOR...at least one program I know decodes but does not transmit packet. It would sure would be great to eliminate one piece of gadgetry from the seat of the truck.

As for the present thread on "reference view" "circles view" "map view" "rectangular view" guys, guys....you lost me a long long time ago!

Now if I could only get rid of my TNC, maybe my wife could sit here in the cab instead of back in the box! Hi

Your claim about "almost nobody" is completey wrong and shows a new-comers bias towards todays shrink-wrapped "maping" packages developed by software programemrs and not by anyone with a background in navigation or radio location. ALL navigation and radio location systems prior to the recent spurt of "MAPS" for "windows" use the concept of "RANGE SCALE". This dates back to 1945 or so. It is technically, sound, it is unambiguous, is familiar to the millions of technicains and operators who have used it throughout these 55 years of use and you will find it on all tactical displays of all RADAR and NAVIGATION systems both military, commercial, Avaiation, and pleasure boats.

RANGE SCALE is a fundamental concept regardless of how distorted some programmers want to display their map views. That is why it is in the APRS spec, to simply serve as a simplest form description so that everyone has an unambiguous reference frame. How you convey it to your users is up to you. Several methods are in use:

- 1) Range circle
- 2) Legend bar across bottom or side equal in length to "range scale"
- 3) Numeric display of current "RANGE SCALE" somewhere on screen.

etc

Bob

Ian's definition of a "reference view" (later withdrawn) has come full circle back to square one. The "term" you are looking for to describe this unambiguous "map/view/reference/geographical area, ETC) is "RANGE SCALE". This is a fundamental descriptor with over 50 years of precedence and common usage.

But Jim's interpretations have pointed out that it did not come across to the reader as clearly as it could have. Thus, I have only slightly re-worded this paragraph to take advantage of all the recent discussion and to hopefully make this concept clear.

> =====

Notice that I changed from LAT/LONG to just CENTER. What one uses to reference the center of a view does not need to be so restrictive.

I can say "Im looking at a range scale of 128 miles around Florence Alabama, and I dont see him anywhere". Or "Im looking around me at 16 miles and cant find him"... In these cases, the "center" is defined in terms other than LAT/LONG.

Also, for your background, Range Scales have always traditionally been integer powers of 2. Usually from about 0.25 miles out to 256 miles. In the 1960's with the advent of computer driven tactical displays including networked target data from other platforms this was extended to 1024 miles. With the worldwide nature of APRS, APRSdos extends that down to .0625 and up to 8192 miles.

I'm confused here, I think using the range circle makes perfect sense.

The problem with the rectangle is it assumes that there is a difference in the X and Y scales.

I don't think that is right. When I look at a map 1 inch (1 cm, whatever) equals 1 mile (1 km) IN ANY DIRECTION.

To me changing the x or y scaling independent of each other would lead to confusion over distances (that wonderful map projection stuff notwithstanding).

I've noticed that the map window in Street Atlas works this way. When you resize the map window it change the area of the map viewed, not changing the scale (SA puts a little bar "|-----|" = 1.0 mile in the status bar of the map window).

Yep, and the smaller that gets the harder it is to estimate distances
across the full map screen. When that little legend is only 1/4 inch long
on a 12 inch screen, it is very hard to estimate things like "looks like
"x" is about 28 miles from me"...

Whereas if you are on the 32 mile RANGE SCALE and the guy is near the
edge, then it is far easier to estimate "28" miles without a ruler...
Thats why I put a RANGE SCALE Legend like this at the bottom of all
APRSdos map views:

|<-----32 statute miles----->|

Which always extends from the center to the right edge of the Range Scale
circle. In this case, I am on the 32 mile range scale. If I have
selected METRIC, then this is shown as:

|<----- 51 Killometers ----->|

Hello Group -

I think what we have here is fundamentally divergent view of technology. I, frankly, could care less what X years of "tradition" has used to describe something, when it does not fit how modern people actually wish to use something.

So, I am willing to put this to rest. I see no resolution.

But, I do have a suggestion for the next rev of APRS standard:

A message format (perhaps as a group "announcement" or "bulletin" - so it can be suitably filtered) containing the necessary coordinates to fully describe a standard "group view". This could contain any set of four coordinates and any member of the group could choose this to automatically set the bounds of their "group view".

This would solve many of the tactical problems which I think Bob is attempting to address. It could be cross-map and cross-application and

cross-platform (provided the programmers supported it); there is no fundamental reason I can see why it could not.

Cheers,

Jim Wagner

>this unambiguous "map/view/reference/geographical area, ETC) is "RANGE
>SCALE". This is a fundamental descriptor with over 50 years of
>precedence and common usage.

I accept that "Range Scale" has been around for a long time, and is associated with a circle that covers a geographical piece of ground.

>
>But Jim's interpretations have pointed out that it did not come across to
>the reader as clearly as it could have.

Jim has said basically that a circle is not the **only** way to define a piece of ground.

>> whatever Range Scale or center is in use).
>> =====

The main thing I don't like about this is the term "map view". A "map view" is simply a "view of a map". As I said yesterday, a user can change that view instant by instant -- views are not fixed as they used to be in radar systems. A "view" relates only to what is seen in a display window (that definition has been around for a long time too), and does not necessarily have any relationship to the "range scale".

Also, you imply that center/range scale is the *only* way to define an area of common interest. Bearing in mind Jim's comments, I think this is too restrictive here, particularly as all of this is an operational issue anyway, not directly related to this spec. Methods of defining areas of common interest belong in another (as yet unwritten) spec.

Hence, merging your thoughts with mine, here is a new replacement section:

~~~~~  
Viewing Geographical Areas of Common Interest

=====

APRS is a tactical geographical system. To maximize its operational effectiveness, users need to have an unambiguous understanding of geographical areas of common interest when communicating with each other.

The usual way of doing this is for users to specify the geographical center and approximate radius of a circle that covers the area of interest. The radius of the circle (in nautical miles, statute miles or km) is known as the "range scale". This convention gives all users a common basis for describing tactical areas of interest, at whatever center/range scale is in use.

The use of center/range scale, or other methods of defining areas of common interest, is an operational issue, outside the scope of this APRS Protocol Reference -- nothing related to these areas is transmitted on-air. However, it is expected that APRS user software will provide easy-to-use tools for defining and viewing these areas, and that operational procedures for communicating them to other users will be put in place.

~~~~~

>
>Notice that I changed from LAT/LONG to just CENTER. What one uses to
>reference the center of a view does not need to be so restrictive.
>
>I can say "Im looking at a range scale of 128 miles around Florence
>Alabama, and I dont see him anywhere". Or "Im looking around me at 16
>miles and cant find him"... In these cases, the "center" is defined in
>terms other than LAT/LONG.

Exactly. That's why I phrased my second para in the new replacement section the way I did.

>

>Also, for your background, Range Scales have always traditionally been
>integer powers of 2. Usually from about 0.25 miles out to 256 miles. In
>the 1960's with the advent of computer driven tactical displays including
>networked target data from other platforms this was extended to 1024
>miles. With the worldwide nature of APRS, APRSdos extends that down to
>.0625 and up to 8192 miles.

OK, but once again this is an operational issue, outside the scope of
this specification.

True, but the APRS SPEC is defining the standard for APRS. As such, APRS needs a standard default way of referring to that common area. And that is RANGE SCALE. Anyone that has been following this discussion sees how absolutely confusing, and ambiguous these discussions can be unless everyone has a common reference. That is the purpose of the APRS SPEC.

Have any of you ever listened to the confusion that reigns as soon as users begin trying to talk about a geographical area, when one is using WinAPRS, one is using APRS+SA, and one is using APRSdos? Its babble. And NO RESOLUTION IS REACHED. They just Argue, each clinging to his own view! WE CANNOT ALLOW THIS TO HAPPEN WHEN APRS IS SUPPOSED TO PROVIDE A STANDARD FOR TACTICAL COMMUNICATION.

This discussion of Rectangles and views is exactly why we must have a single default reference. And it MUST be in the SPEC. Ian's proposed wording is too watered down and will not accomplish the objective. I have revised Ian's proposed wording to meet these objectives.

If Jim wants to propose that users in the future may refer to the 4 corners of an area, that is OK for later versions, but I doubt any voice users are going to say...

"Im looking at a box with the following corners of LAT/LONG and LAT/LONG and LAT/LONG and LAT/LONG and I dont see the truck anywhere.."

Compared to "Im looking out 32 miles from me and dont see him"...

Or "Does anyone see an Ambulance within 10 miles of the fairground???"

On Mon, 15 May 2000, Ian Wade wrote:

> >I think what we have here is fundamentally divergent view of technology.

It has nothing to do with technology. It has to do with human communications in describing their VIEW, INDEPENDENT OF TECHNOLOGY! It is the cross platform / cross medium conveyance of unambiguous information that I am concerned with.

Who have you heard refer to an area on a voice repeater by giving the LAT/LONG of the corners of the box? I have never heard any... But I do hear ALL THE TIME, comments like "He is within 10 miles of there"... etc... Or "I'm 57 miles outside of Denver"...

> >A message format (perhaps as a group "announcement" or "bulletin" - so it
> >can be suitably filtered) containing the necessary coordinates to fully
> >describe a standard "group view". This could contain any set of four
> >coordinates and any member of the group could choose this to automatically
> >set the bounds of their "group view".

This paragraph shows a total misunderstanding of the concepts here. We are NOT TRYING to force a common "group view" AT ALL. That is why I don't like this movement of Ians's to a REFERENCE VIEW nor to a GEOGRAPHICAL AREA. It is diverging from the fundamental concept of being able to describe MY VIEW. And that means my IMMEDIATE, This-Instant view in a SIMPLE and UNAMBIGUOUS WAY.

When I say I am looking at Washington DC on the 128 mile range scale this has NOTHING to do with what anyone else is using, or seeing, or interested in... But it tells *YOU* THE LISTENER, WHAT *I* SEE. This is the concept I am trying to get across. We will all have countless views at ANY INSTANT in time. But every such VIEW must have a way to describe it SUSCINCTLY.

If I say I am looking at Washington DC on the 128 mile RANGE SCALE and Joe is looking at Baltimore on the 64 mile range scale, then anyone with a minds eye can "see" their common areas of coverage...

I dont know anyone that can visualize the common area of two Boxes specified by a total of 8 LAT/LONG pairs. That is rediculuuous and will never be used by voice communicators.

So I am going back to my original definition. That we are talking about a PARAMETER to describe a "VIEW". We may both be interested in the whole state of Maryland duing an STATE emergency, but at any instant, I must be able to say suscinctly and unambiguously where I AM LOOKING and to what SCALE.

There is no other simple method that fulfills this requirement. Period. If we want, I have no objection to allowing differing "N/S and E/W" range scales to describe oblong views if someone finds that useful.

Here is that wording...

```

Ah, but now I have renigged. I see now that we are still talking about two different things. SO I am back to describing VIEWS which was my original intent... Sorry... Your logic was clever and lead me off track.... :-)

But now that I see where we have arrived... it ain't where I was headed... so to speak.

Bob

In article <LYR14779-84052-2000.05.15-11.28.24--Ian.Wade#care4free.net@lists.tappr.org>, Bob Bruninga <bruninga#nadm.navy.mil> writes

>Ah, but now I have renigged. I see now that we are still talking about
>two different things. SO I am back to describing VIEWS which was my
>original intent... Sorry... Your logic was clever and lead me off
>track.... :-)

There was certainly no intention of trying to be clever! I just want to remove the confusion that your original version caused.

Problem is, we have now returned to the reason why Jim got confused in the first place. Bottom line: the term "map view" is totally irrelevant, confusing and meaningless in this context.

I look at a map, and decide the center/range scale. I tell you the center/range scale. We now both understand exactly which bit of *ground* we are talking about. That's the object of the exercise.

But I do *not* tell you which bit of your *map* to *view*. Your "map view" is whatever part of your *map* you choose to view. You can

pan/zoom/change your window size at any time to get a different "map view". Your "map view" may not even contain *any* of the bit of ground we agreed on. All of this is a display issue and nothing to do with the spec.

A "view" is what you see in a window. Nothing more. It is *nothing* whatsoever to do with the center/range scale area.

Group -

With some trepidation, I need to respond to Bob's response of 5-14-00.
I will try, very hard, to avoid assertions about character or
personality. I hope that I am successful! If I am not successful,
please remember that no malice is intended. Here, first, is the
statement that triggered the response:

>> I, as a user and programmer, will not accept the second. The first
is
>> nearly trivial but is a pain in the rear to have to do when its not
>> necessary and when (almost) nobody else does it.

And, here is Bob's response:

>Your claim about "almost nobody" is completey wrong and shows
>a new-comers
>bias towards todays shrink-wrapped "mapping" packages developed by
>software
>programemrs and not by anyone with a background in navigation or radio

>location. ALL navigation and radio location systems prior to the
>recent
>spurt of "MAPS" for "windows" use the concept of "RANGE SCALE". This
>dates back to 1945 or so. It is technically, sound, it is
>unambiguous, is
>familiar to the millions of technicians and operators who have used
it
>throughout these 55 years of use and you will find it on all tactical
>displays of all RADAR and NAVIGATION systems both military,
commercial,
>Aviation, and pleasure boats.

>RANGE SCALE is a fundamental concept regardless of how distorted some
>programmers want to display their map views. That is why it is in the
>APRS spec, to simply serve as a simplest form description so that
>everyone
>has an unambiguous reference frame. How you convey it to your users
>is up to you. Several methods are in use:
>
>1) Range circle
>2) Legend bar across bottom or side equal in length to "range scale"
>3) Numeric display of current "RANGE SCALE" somewhere on screen.

I found this assertion quite incredible.

To provide a "reality check", I surveyed 10 acquaintances. All are map users and use maps in ways in which their life, or the life of someone else, depends on it.

3 are pilots (all private, one IFR), one originally licensed in 1975.
2 mountain rescue volunteers
2 mountain climbers who are not involved in mountain rescue
1 sea kayaker who uses coastal navigation charts
1 mountain biker who leads bike tours in Hawaii
1 County Sheriff's Deputy who works with search and rescue
1 Aquatics Biologist/Ham (who does flood hazard assessment, among other things)
2 4-Wheel Drive search/rescue people (2 hams)
2 Backpackers (1 ham)

[note: this adds to more than 10 because some people fall into several categories]. One is former military (Deputy). Most are under 50 and all are under 60. A few are under 30. Not one of these is among the "millions of technicians and operators" described by Bob.

1. Not one has heard of "Range Scale" associated with a map.
2. Two (other than pilots) have used a compass for navigation purposes.
3. Two have tried to find their location on a paper map using GPS.

4. All know that their "good" maps have lat/lon scale on map edges.
5. When explained, all pilots relate "Range Scale" to OMNI "rose" printed on their nav charts. But, when confronted with the idea that "Range Scale" somehow described the size, extent, etc, of a map, all responded with a "blank" and/or "What good is it?"
6. Not one of the pilots has flown an aircraft with a Range-Scale display in the cockpit. Single-engine private aircraft don't usually carry RADAR.
7. One non-pilot, when prodded, did associate it with a circular RADAR display.
8. All are computer users.
9. Several were experienced DOS users but not one willingly uses it now.
10. When asked about software to view "maps" on a computer screen, all preferred a windows-oriented environment where they could have other windows from other applications present, allowing them, for example, to record notes related to the situation at hand.

Folks, these are the real-world people who we have to work with in real-world emergencies. These are also representative, I believe, of most new-comers to ham radio, and thus, fairly representative of in-coming APRS users. To think otherwise, it seems to me, leads us only down the path of narcissism. Do we really want to develop yet another tool which has little real-world use and is thus, hardly more than a toy for our ham amusement.

The (repeated here) assertion:

```
>shows a new-comers  
>bias towards todays shrink-wrapped "mapping" packages developed by  
>software programers and not by anyone with a background in navigation  
>or radio location.
```

is a real key to this discussion. People use mapping packages developed by software programmers (who else would develop the packages?) because they are easy to use. Yes, they are "biased"; they LIKE the software and they use what they like! To decry this situation is rather like decrying the lack of use of CW. It fails to recognize changes in technology and changes in the technology user-base. If we do not recognize this situation and fail to cope with maps "that can be stretched every which way", then APRS will go the way of other technologies which "were promising but never made it".

I, personally, DO have a background in navigation. But not military. My navigation is as a private pilot, mountain climber, & sometimes orienteer. To me, the idea of "Range Scale" is simply useless because it does not fit what people want to do with their tools.

To press the analogy, over 55 years of experience showed that tires needed inner tubes. Several hundred years of experience showed that wheels needed steel rims. Many years of experience showed that frequencies "down" from 2000 meters were useless. Lets not get caught up in the arguments about "what has been used for 55 years"!

To force the APRS display into the mold of RADAR, is, I believe, at the very least, short-sighted. We are clearly stuck with the existing definitions for now. However, they do not have to stay that way. A Version2 protocol should come out, just like AX.25 got revised early-on and became AX25L2V2. Display management should be high on the list of issues for APRS_V2.

Respectfully,

Jim Wagner, KA7EHK

In the MIC-E chapter, there are two "TM" symbols where there should be a ">=". Page 50, at the bottom. At least in the PDF version. Don't know about the Word version, and don't care.

I see some more misplaced "TM" symbols on page 51, so perhaps they are throughout the document?

I DISAGREE 100%. Caps added for emphasis of key words only...Im not Shouting, hi hi..

Forget all that has been said. Start with a clear and open mind. The "concept" I am trying to quantify with this CENTER/RANGE SCALE is a way for ANY user, looking at ANY map, or view ON HIS COMPUTER to be able to DESCRIBE what HE sees to any other user by APRS, voice or any other communications medium suscinctly and in an expected, simple, and common format.

It has NOTHING to do with "areas of interest"
It has NOTHING to do with "common geographical areas"
It has NOTHING to do with anyone else's MAP, VIEW, or WINDOW
It has NOTHING to do with what the receiving station, sees or views....

It is ONLY a SIMPLE METRIC for ME to describe MY VIEW, that is to say, "what I am looking at". SO that if YOU need to know what I am looking at, I have given you all that you need to know to UNDERSTAND what I am seeing...

If I say I am looking at a view centered on "X" with a RANGE SCALE of "R" miles then NO ONE under the sun can MISSINTERPRET that. Period.

Now if Jim wants to have a view that is 1000 miles wide and only 100 miles tall, then he can say that he "is looking at a view CENTERED on "x" with a N/S RANGE SCALE of 50 miles and and E/W RANGE SCALE of 500 miles."

AGAIN, there is NO CHANCE for missinterpretation of what He is looking at.

On Mon, 15 May 2000, Ian Wade wrote:

> Problem is, we have now returned to the reason why Jim got confused in
> the first place. Bottom line: the term "map view" is totally irrelevant,

I disagree 100% in what I am trying to describe.

> I look at a map, and decide the center/range scale. I tell you the
> center/range scale. We now both understand exactly which bit of *ground*
> we are talking about. That's the object of the exercise.

I would say it describes what "I" am talking about in an unambiguous way, It says nothing about what the receiving station is looking at, or even interested in. Thats up to him. But at least he now KNOWS what "I" am

looking at unambiguously...

> But I do **not** tell you which bit of your **map** to **view**. Your "map
> view" is whatever part of your **map** you choose to view.

Agreed absolutely.

> You can pan/zoom/change your window size at any time to get a different
> "map view". Your "map view" may not even contain **any** of the bit of
> ground we agreed on.

REMOVE any CONCEPT of the "ground we agreed on". That has nothing to do with this CENTER/RANGE concept. CENTER/RANGE is only a way of describing (quantifying) a VIEW from the SENDER's perspective. There is nothing required, assumed, or inferred on the part of the receiver to do anything with this data. But it is there, in an UNAMBIGUOUS way for his use if needed.

> All of this is a display issue and nothing to do with the spec.

I DISAGREE COMPLETELY. The APRS SPEC is a standard for APRS communications. The SPEC is full of such STANDARDS so that INFORMATION is conveyed UNAMBIGUOUSLY from the sender to the RECEIVER... The presence of MAP VIEWS throughout ALL versions of APRS software is the single most salient characteristic of APRS compared to all other PACKET radio.

THEREFORE, We MUST have a common, standard METRIC to describe those views to OTHERS as WE see them.... CENTER/RANGE-SCALE is that METRIC.

> A "view" is what you see in a window. Nothing more. It is **nothing**
> whatsoever to do with the center/range scale area.

I disagree 100% completely! It **is** THE MEASURE, the way of QUANTIFYING the size of that VIEW. Nothing more, nothin less.... It will change as often as I change my VIEW. But no matter what it is at any instant, it is

- 1) Complete
- 2) Unambiguous
- 3) Simple
- 4) Well understood.
- 5) Concise

in describing what the SENDER wants to convey when he says...

"I am looking at "X" with a RANGE SCALE of "Y" and I see (or dont see)
"Z"...

I say again, I know of no other METRIC that is as simple, concise, unambiguous, and well understood as the above. By including the provision

for N/S and E/W range scales we can even describe the rectangular views as well..

And FINALLY, this is not some academic exercise. It is MY EXPERIENCE of 9 years of seeing APRS used in the FIELD to support events and REAL applications where OPERATOR CONFUSION runs RAMPANT between different operators trying to resolve the location of something that they BOTH see or DONT see on their respective SCREENS.

They MUST HAVE A COMMON WAY TO DESCRIBE the SIZE of WHAT THEY ARE LOOKING AT... Using CENTER and RANGE-SCALE is that WAY.

Just look at Jim's examples. This confusion happens ALL THE TIME...

de WB4APR, Bob

On Mon, 15 May 2000, James Wagner wrote:

> 1. Not one has heard of "Range Scale" associated with a map.

I am not talking about MAPS. I am talking about ELECTRONICALLY PRESENTED VIEWS of geographical data.

> 3. Two have tried to find their location on a paper map using GPS.

Yes, but WHAT method have they used to "COMMUNICATE by any other means" to tell someone else (remotely) in the blind about the "size and scale" of the map they are using? If they are using a 1:10,000 QUAD and someone else is using a EXXON State Highway map, then I bet dollars to DONUTS that they cannot make sense to each other about what they SEE on the map without CONVEYING the difference in their map views....

> 4. All know that their "good" maps have lat/lon scale on map edges.

To what scale? I have a chart of the East Coast of the USA with LAT/LONG, and I have a harbor chart of Annapolis with LAT/LONG and two "in the blind" users of these two maps will see NOTHING AT ALL in common...

> 5. When explained, all pilots relate "Range Scale" to OMNI "rose"
> printed on their nav charts. But, when confronted with the idea
> that "Range Scale" somehow described the size, extent, etc, of a
> map, all responded with a "blank" and/or "What good is it?"

Its not a MAP. Its an "ELECTRONIC VIEW" which can range over 8 orders of magnitude of scale. Put two such pilots on two ends of TELEPHONE. Give one a SECTIONAL chart and one a RUNWAY chart of the local airport.. and ask them to talk about something they see on their chart. The FIRST Thing they will do when they realize they are looking at two different views is to somehow REFERENCE their chart to the OTHER guys chart. It may be subtle, but until they somehow communicate a REFERENCE, thew will be hopelessly confused...

> 6. Not one of the pilots has flown an aircraft with a Range-Scale
> display in the cockpit. Single-engine private aircraft don't usually

> 8. All are computer users.

So, then, we have a pilot, looking at a MAP/CHART/VIEW in his aircraft and I see on my PC/MAP/WINDOW/VIEW a map of ARBITRARY size, scale and location.... How do I know what the PILOT is looking at when he asks if I see "X"? How far away is it? From Where? What SCALE is he viewing?

> 9. Several were experienced DOS users but not one willingly uses it

Great. No problem, but HOW do they CONVEY what THEY are looking at to
SOMEONE else?

> down the path of narcissism. Do we really want to develop yet another
> tool which has little real-world use and is thus, hardly more than a
> toy for our ham amusement.

The only alternative that you have offered to CENTER and RANGE to
unambiguously describe a MAP VIEW is to require an 8 valued metric
of the LAT/LONG of the four corners of the view.

I say that your proposal for the APRS common way to Quantify a VIEW by
the LAT/LONG of the four corners is:

- 1) Not concise
- 2) Not easy to visualize in scope or scale
- 3) Not easy to refer to a central point of reference
- 4) Unwieldly and prone to grievous errors when passed by voice
- 5) Inconsistent with the STATION-CENTRIC physics of radio communication
- 6) etc...

> is a real key to this discussion. People use mapping packages developed
> by software programmers (who else would develop the packages?) because
> they are easy to use. Yes, they are "biased"; they LIKE the software
> and they use what they like!

These are self-relevant APPLICATIONS. They are NOT used in a real-time,
multi-user, multi-view, network of disjoint users all using a DIFFERENT
map system and set of maps. I will BET that any such NETWORKED use where
all users on the network need to communicate about WHAT They see on their
georeference system will have SOMETHING like:

REGION

MAP NAME

MAP SCALE

ZOOM FACTOR

MAGNITUDE,

or any of a number of other ways to communicate the SIZE of any
particular VIEW among users..

If they dont, then they will.... once they try to let humans use them in

an ON-AIR scenario...

> technology and changes in the technology user-base. If we do not
> recognize this situation and fail to cope with maps "that can be
> stretched every which way", then APRS will go the way of other
> technologies which "were promising but never made it".

Stretch them any way you want. The CENTER and RANGE (allowing for a separate N/S and E/W component) still seems to me to be the simplest, most concise and most useful descriptor of a station-centric or object-centric or interest-centric view...

> To me, the idea of "Range Scale" is simply useless because
> it does not fit what people want to do with their tools.

How then do you convey to a distant "dissinterested" observer what "map/view/scale/window" you are currently referring to?

> To force the APRS display into the mold of RADAR, is, I believe, at the
> very least, short-sighted. We are clearly stuck with the existing
> definitions for now.

But Jim, I think you have contributed greatly by causing us to expand the definition, to include a N/S and E/W component of range scale for maps that are not well suited to a single range descriptor. Also, you have forced me to clean up my wording and focus only on the concept of a single VIEW METRIC. I appologize for getting frustrated at not being able to get others to see such a clear and simple concept.

Funny. Every map I ever looked at had one. They are usually called scales,
since calling it a range scale is a bit redundant.. (x feet per inch or
some such)

Bob and everyone.

I had hoped to let this lay, but I think I see some common ground here.

In my terms, Bob seems to be describing Range from some location. The hang-up is that the location has nothing to do with the CENTER of the map/view.

So long as you have some method for readily determining the coordinates of some reference point (say, just for example, mouse-clicking with a cursor at the point in question) and some ready method for determining the distance from there to some other point (say, by dragging your cursor between the two, just for example), then you would appear to satisfy Bob's requirement.

If this is correct, the whole idea of "range" has nothing to do with the distance from the center of the map to its nearest edge. Or the extent of the map view. Or the scale of the map. Or any of these other things. It is simply the distance from the reference point and some other point in question.

Cheers,

Jim Wagner

No. Bob seems to be describing it now as the center of his "map view"
(i.e. the center of what he sees in his display window), not the center

of a piece of ground. Others could care less about what Bob can see on his screen -- they just want to know what on-the-ground geographical area he is referring to. That's why "map view" is meaningless.

Exactly. The reference point is a point on the ground. It is not a point on the display. It is not a point on the "map view".

Bob and everyone.

I had hoped to let this lay, but I think I see some common ground here.

In my terms, Bob seems to be describing Range from some location. The hang-up is that the location (as he described it in his examples) has nothing to do with the CENTER of the map/view.

It seems to me that Bob's requirement would be satisfied if:

(1) There some method for readily determining the coordinates of some reference point. Just for example, it might be mouse-clicking with a cursor at the point in question.

(2) There is some ready method for determining the distance from there to some other point. For example, it might be as simple as dragging the cursor between the reference point and some other point in question. Or it might be clicking a "distance" button, then clicking a point in the view with the software determining the distance from the clicked point to the reference point.

If this is correct, the whole idea of "range" has nothing to do with the distance from the center of the map to its nearest edge. Or the extent of the map view. Or the scale of the map. Or any of these other things. It is simply the distance from the reference point and some other point in question.

Could it be that we have been discussing entirely different things without recognizing it?

Cheers,

Jim Wagner

No, it has EVERYTHING to do with the CENTER of the MAP VIEW of the person

who is referring to it... That is its definition... Ian's attempt to tie that location to a piece of ground in a "reference area" lead us all off on a tangent... and everyone else seems to still be thinking along those lines... I have returned to the original concept of simply a METRIC for describing the LOCATION and EXTENT of a view. ANY view.

> If this is correct, the whole idea of "range" has nothing to do with the
> distance from the center of the map to its nearest edge. Or the extent of

>
> Could it be that we have been discussing entirely different things without
> recognizing it?

Yes, and we still are. Please understand I am talking about only the METRIC to be used to describe the "location and extent" of MY "current" MAP VIEW. "MY" in this case is WHOEVER wants to "describe" his own view to someone else...

In this context. The CENTER of that "view" describes the "location" of the view and the "RANGE SCALE" describes the "extent" of that view.

NOTHING MORE. I have seen only the following other alternatives as a METRIC for anyone to use to describe their "current" view.

- 1) CENTER and RANGE (can have N/S and E/W components if needed)
- 2) LAT/LONG of all four corners

This discussion should have proved to EVERYONE the importance of having a common method of describing views. If we cannot understand what the other of us is saying about a view, then how can we possibly expect the users to make sense across all platforms and views and scales and in the heat of operations.

It appears that each author is still thinking that everyone is using ONLY their software. Then in most cases there is consistency. But PLEASE try to put yourself in the USERS shoes who is trying to visualize what Someone else using someone elses software is looking at. Close your eyes. What is the simplest way to do that?

I maintain that referring to the CENTER and RANGE of the view is the simplest and most concise way...

Bob

These sound like really useful, intuitive GUI features, (although you should provide provide heading as well as distance).

I will admit that, even on re-reading the "Range" discussions, much of it doesn't make a whole lot of sense, particularly compared to Jim's

suggested solution above.

All this discussion reminds me of the manual inputs days of the Air Defense Command. Your PPI had a center, and you could click a range switch, or offset the center of the sweep. This was all replaced by vector displays (and then raster) that show a map that covers the most area with the least distortion. You can roll your track-ball and the cursor can be used to "hook" any point, press the offset button to center, and then zoom in or out in binary (2x, 4x, 8x, 16x, 32x). You basically roll/offset to pan the view. I still think this is pretty much an obsolete model (1930's).

I like the UI-View method. You don't have to worry about zooming in and out. You make a map of the area you want (special event, static, etc) and that's what you see. I think it is the logical modernization of the PPI scope model.

One of the interesting things you see about a scope operator, is they tend to use the same scale out of habit. The people who actually look around for unknown targets, usually have a large scale and then offset and zoom to the area where they see something. This is the same as offsetting and selecting a new map with higher resolution.

But say they put a track on the object. The computer then transmits the track block to others based on its lat/lon. It has no concept of center, scale, or range. The distant receiver of the track block can display it any way they like; indeed, they do.

Steve/k5okc

To try to show you exactly what I really want to see on ALL APRS views as a common frame of reference for ALL users of ALL software is the following.... Please use a FIXED FONT to see this:

- 1) Somewhere on the VIEW, display a LEGEND that extends from the CENTER OUTWARD with a length equal to the largest integer power of 2 that will fit. The RANGE SCALE is the length of that LEGEND.
- 2) Somewhere on the VIEW, display the LAT/LON of the center & that RANGE.

[illegible]

Notice that you can zoom to ANY size , ANY shape, but as long as we all display the largest integer power of 2 RANGE that will fit on each view then we all have a basis for common communications. I am Perfectly OK with Jim's long maps too. In this case he would display:

[illegible]

His user would say he is "on a 64 mile range scale" from X. The user has a clear frame of reference as to what is within range of this view even if it is squished.

Further, I dont care whether you put the RANGE SCALE LEGEND in any of the other 8 orientations, or horizontal or vertical, as long as ONE END is referenced to the center... The KEY is that the view is more-or-less quantified by only TWO parameters, CENTER and RANGE SCALE.

What I do **not** want to see is this:

A rectangular box with a dashed border. In the bottom right corner, there is a scale bar consisting of a horizontal line segment with vertical tick marks at each end, labeled "10mi".

How do I describe this to anyone???

Where on the planet are we? What is the center?

Its hard for me to instantly grasp about how wide this view is.

Will something reported as 60 miles away from me be on this map?

It is just not clear for use in a network of dissimilar users all with different views and all needing to communicate rapidly and concisely.

Hope this helps..

Bob

P.S. It DOES NOT HAVE TO BE MILES. It can be Statute miles, Nautical miles, or Kilometers. But whatever it is, it should be the largest integer power of 2 that will fit. It doesnt even have to be integer powers of two. Though I prefer that as a simple descriptor of magnitude. If your range scale is 50 miles. I have no problem with that. Just display a LEGEND that is 50 miles long.

I hope it might help to have a specific example to discuss. How about a view centered at 3853.83N/07702.30W with a Range Scale of 1 Nautical Mile. Do you see the Lincoln Memorial? Do you see the Washington Monument? I'd describe this view with Jim's 4 corner points too if I could figure out just how to do that. Maybe Jim will provide them for discussion purposes. Just thought an example might help.

Here's what I see:

<http://www.usa-site.net/~ssampson/sample.gif>

(GIF is 50k)

I see both, but I can't see Kennedy Center, or
Chinatown Arch.

More differences between APRServe and APRSd. APRServe echos all packets, even those sent to it by your local station. APRSd does not! I send it a packet, it is not ever echoed back by APRSd. Everything else still works, I can send message to other stations, I can be seen, RF gating appears to work, but I can not see my own packets, or any packets my station might send to APRSd. It is like transmitting on RF, and knowing you are getting out, but never seeing a digipeated packet.

3rd party messages. One of the fundamental designs of the third party packet and APRServe was that APRServe would ignore them. That has changed with APRSd. I have modified the current version of APRS+SA to remove them. Yes, that is simple. I just wanted you to be aware, APRSd is not equal to APRServe.

www.aprs.net == APRSd
second.aprs.net == APRServe.

Hello everyone -

This has gone on far too long. We seem to have gone around several times and I am confused.

I will implement Center and Range indication in my maps in any way that the spec gets written. But, I will also provide other tools which (hopefully) provide even better information.

Cheers,
Jim, KA7EHK

A more proper analogy is its like connected mode RF as the underlying TCP layer is handling retries/confirmation of receipt.

In article <LYR14779-84425-2000.05.17-01.20.20--Ian.Wade#care4free.net@lists.tapr.org>, Jim Wagner <wagnerj@proaxis.com> writes

>
>I will implement Center and Range indication in my maps in any way that the
>spec gets written. But, I will also provide other tools which (hopefully)
>provide even better information.

There may be a few words in the spec on the *philosophy* of Center and Range, but there will be nothing about its *implementation*.

Within the scope of APRS Protocol Version 1.0, implementation of Center and Range is a display/operational issue, not an on-air issue. So the way is wide open for you to develop those tools.

BTW, you can add my name to your list of people who have come across "Range Scale" -- at one time I was in radar system design (but that was 35 years ago, in the last century <grin>).

I disagree completely. Specifying a metric for MAP VIEWS is a STANDARDS
issue of the 1st degree of importance. It must be in the spec.

By the way, ON further thought, I also dont even care if the RANGE SCALE
LEGEND has one end on center. Just so long as SOMEWHERE on all
views is the following information. I DONT EVEN CARE IF WE CALL IT "RANGE
SCALE" But it MUST have the word "SCALE" in it.

LAT of center
LON of center
RANGE SCALE *or* SCALE

Where RANGE SCALE is simply defined as a LEGEND of length N mi|km|nm
which is approximately the distance of the smaller of the

half-width/or half-height. Thus even the following would be fine...

+-----+	So You can put it ANYWHERE, ANY oreintation
RNG	ANY thing you want, AND it doesnt even have
LAT	to be an integer power of 2. But the length
LON +	is important to be about HALF screen.
<- 32 mi ->	
+-----+	

Surely we can agree on this standard METRIC for defining !@#\$\$% SCALE!
IF JIM's users have such a problem understanding "RANGE" then we can JUST
CALL IT SCALE!!! I DONT CARE. But we MUST HAVE A STANDARD for
describing the extent of a "VIEW" in APRS. CENTER and @#\$\$%! SCALE are
the best way that I can think of.

Trying to do such a simple thing with a list of FOUR LAT/LONGS is
rediculuos. How many people can tell you if I can see a station 30
miles away if I tell you that the corners of my view are

3859.13N 07629.11W
3845.22N 07629.11W
3845.22N 07619.32W
3859.11N 07619.32W

Very precise but practically useless to human operators.

Whereas "my view is on a 32 mile range around Glen Burnie" is MUCH more
user friendly.

Bob

Authors,

This one is short. please take time to read it. It REMOVES RANGE! Thanks. Here is another try at a suggested wording that would be acceptable to all authors:

REFERENCE FOR MAP VIEWS:

> APRS is a tactical geographical system, and users need to be able to
> relate the size of a map view in a non-ambiguous way. Thus all map
> displays should have a meaningful legend to convey the SIZE of the map
> view to the users that is consistent across all applications.

> Thus when communicating about such views, two parameters are
> required: CENTER and SCALE.

>

> In this context, the SCALE of any map view is the approximate
> range (in nautical miles, statute miles or km) of the largest circle
> that will conveniently fit in that map view. This SCALE should
> be presented to the user with a LEGEND of that length somewhere
> on all views. This convention gives all software users a common
> and concise basis for describing the approximate size of the
> central region of all tactical map views across all platforms.

Bob,

I think I finally understand. I think the discussion so far has been mixing up two things. The Map View is what a user can see on his/her display at a point in time. That is what is defined below. And Area of Interest which the area that is involved in the activity being "managed" by APRS. It is up to the user what Map View they use so what you are trying to standarize is a common definition of the contents of a Map View so that two users talking to each other can agree that they at least have a common subset of the total APRS picture being displayed on their displays. Is this correct?

Yes. But I would say the last sentence as... "can both have a scale of reference when they talk about the APRS picture being displayed on their displays..."

Ian and the group,

In my last posting, I focused only on the fact that I want a common "SCALE" of reference, for all map views. I removed all references to range except that it is simply used to define the approximate size of this Scale. In this sense it does make sense to include the word as an adjective modifier. The below only has one word changed from my posting earlier today... It is my preferred wording.

On Wed, 17 May 2000, Bob Bruninga wrote:

This wording should be ambiguous enough for those authors and users who are confused by the term RANGE and they can just use SCALE. But those who do understand the concept of range, can use the term RANGE SCALE as a better descriptor of the "scale" that they are using.

Bob

Nice sample.gif, Steve. I think our datums are different, and it shows at this Scale. On my Washington, D.C. map using the maplist.eas DOS map with APRSdosMAX846, I see the given Center as the White House building

itself. I bet my map uses NAD27 and yours uses WGS84. Close though.

What does "range ... of the largest circle" mean? How can a circle have
a "range"? (It can have a *radius*, as I wrote originally).

>> > that will conveniently fit in that map view.

Why does the circle have to fit into anything on the screen?

> This RANGE SCALE should

>This wording should be ambiguous enough

You can say that again. It *is* ambiguous.

I'm sorry Bob, but this won't do. You are still introducing noise about
"map views" which is of no interest to other users. Nobody is interested
in what "view" you have of your map on your screen. Nobody is interested
in whether that view fits your display window or not. Nobody is
interested in what kind of bar representing distance/range you display

in your window.

What people need to know is simply what *geographical area* you are referring to, which you *can* represent uniquely and unambiguously by center/range. That is all.

~~~~~

With this information, people can then decide which map they need, how they want to display it, and what scale bar (if any) they want to have displayed somewhere in the window. The "view" on their screen may finish up looking exactly like yours, but it doesn't have to.

~~~~~

This is where your definition falls down. By all means talk about a "map view" (provided you define the term, which you haven't), but don't relate it in any way to display geometry or display "views".

A few days ago, you presented a different form of words (just before you thought I'd tricked you with my fiendishly cunning logic :-)):

```
>> COMMUNICATING Geographical Areas of Common Interest
>> =====
>> APRS is a tactical geographical system. To maximize its operational
>> effectiveness, users need to have an unambiguous understanding of
>> geographical areas of common interest when communicating with each
>> other.
>>
>> In APRS, this is done by reference to a CENTER and RANGE. These

>> covers the area of interest. The radius of the circle (in nautical
>> miles, statute miles or km) is known as the "range scale". This
>> convention gives all users a simple common basis for describing tactical
>> areas of interest, at whatever center/range scale is in use.
>>
>> For interoperability among all platforms and modes of communications, it
>> is expected that APRS user software will provide easy-to-use tools for
>> defining and viewing these areas of tactical interest.
>> ~~~~~
>
```

I said I would plug this into the spec, because I believe it covers all the points you've mentioned. It *is* ambiguous enough to allow different methods of specifying a geographical area of interest, *without* being needlessly prescriptive on how people relate it to their display views.

~~~~~

I still say that this earlier definition of yours is the best so far, in the context of the "APRS Design Philosophy" chapter in the spec.

~~~~~

In article <Pine.GS0.4.05L.10005170949380.620-1000000@arctic>, Bob Bruninga
<bruninga@nadm.navy.mil> writes

>By the way, ON further thought, I also dont even care if the RANGE SCALE
>LEGEND has one end on center. Just so long as SOMEWHERE on all

>views is the following information. I DONT EVEN CARE IF WE CALL IT "RANGE
>SCALE" But it MUST have the word "SCALE" in it.

No. The "scale" relates to how big something is displayed in a window.

The "range" relates to how big something is on the ground.

```
>
>Where RANGE SCALE is simply defined as a LEGEND of length N mi|km|nm
>which is approximately the distance of the smaller of the
>half-width/or half-height. Thus even the following would be fine...
>
>+-----+ So You can put it ANYWHERE, ANY oreintation
>|RNG      | ANY thing you want, AND it doesnt even have
>|LAT      | to be an integer power of 2. But the length
>|LON      + | is important to be about HALF screen.
>|          |
>|          |
>|      |<- 32 mi ->|
>+-----+
>
```

Why should the range scale be related in any way to the screen geometry
(i.e. half-height/half-width)?

The following 2 pictures show the "view" to exactly the same *range* as your
picture, but to a different "scale".

```
+-----+
|RNG      | ZOOM IN
|LAT      |
|LON      + |
|          |
|          |
| |<-----32mi----->| |
+-----+

+-----+ ZOOM OUT
|RNG      |
|LAT      |
|LON      + |
|          |
|          |
|      |<32mi>|
+-----+
```

This last picture could also be viewed like this:

```
+-----+
|RNG      |      ZOOM OUT, PAN LEFT
|LAT      |
|LON      |      +
|          |
|          |
|          |
|          |      |<32mi>|
+-----+
```

(i.e. the geographical center is not at the screen center.

In other words, all of the 4 above screen "views" are **different**, but they all represent exactly the **same** geographical area of interest, using the **same** range.

Thus it does not make any sense to talk about your screen "view". You need to talk about the **geographical area**, on the ground.

>
>Whereas "my view is on a 32 mile range around Glen Burnie" is MUCH more
>user friendly.

No problem at all with that, because you didn't use the word "scale", and you didn't specify how much of that view occupied your display -- your use of the word "view" here does not relate to screen scale or screen geometry.

I repeat: "view" and "scale" are screen/display/window artefacts, associated with zoom and pan actions, and are irrelevant to this discussion.

"Center" (=Glen Burnie) and "range" (=32 miles) relate to a geographical area, and are directly relevant to this discussion. But anyone using that information is free to "view" it and "scale" it any way they want -- this is not for the specification to decree.

I wasn't going to join in this discussion, but...

I don't like this new version for two reasons (I'm assuming that where
you have put "range" of a circle you meant to put "radius".)

1. There are common usages of the term SCALE when referring to a map
that are different to your definition. E.g. "this map has a SCALE of
1:250,000", or "this map has a SCALE of one inch to five miles". I think
this proposed usage of the term SCALE will confuse users.

2. I don't like the insistence on the scale legend. On unprojected maps
drawn on a rectangular lat/long grid, as commonly used by APRS software,
such a scale is always inaccurate, and it becomes increasingly
inaccurate as the area covered by the map increases, to the point where
it contains no useful information. I don't think a requirement to show
such a line should be part of the spec.

So I think SCALE should be RANGE or RANGE SCALE, but not just SCALE on
its own, and the requirement for the scale legend should be removed.

That leaves a simple requirement for something like:-

Map centre - 5258.24N, 00002.77W
Map range (or range scale) - 50 miles

(RANGE or RANGE SCALE defined as you have defined SCALE.)

The RANGE of a circle is equivalent to its radius.

> >> > that will conveniently fit in that map view.

Because that is the metric for deciding what is the appropriate SCALE for
that map view.

No one may care, but when they DO, then I NEED A METRIC TO DESCRIBE IT TO
THEM!

> What people need to know is simply what *geographical area* you are

~~~~~

NO!!!!!! I am NOT describing a geographical AREA!!!!!! I am describing  
WHAT I SEE ON MY SCREEN!!!!!! This is so that I can CONVEY that to another  
user. \*\*\*\* BIG DIFFERENCE!!!!

> With this information, people can then decide which map they need, how

~~~~~

ABSOLUTELY. They can LOOK AT ANYTHING THEY WANT. I am using CENTER AND SCALE AS A METRIC TO DESCRIBE WHAT **** I **** Am LOOKING AT. FORGET YOUR CONCEPT OF A FIXED GEOGRAPHICAL PIECE OF GROUND. THAT IS NOT WHAT I AM TALKING ABOUT.

> This is where your definition falls down. By all means talk about a "map

I disagree. It is ambiguous, refers to geography and not map views, and does not convey the sense of importance of having a common standard METRIC for describing map views.

Im GONE TO DAYTON. NO MORE COMMENTS TILL NEXT WEEK.

NO, WRONG, INCORRECT. It is the radius of the largest circle that will fit on a screen.

> >Where RANGE SCALE is simply defined as a LEGEND of length N mi|km|nm
> >which is approximately the distance of the smaller of the
> >half-width/or half-height. Thus even the following would be fine...

```

> Why should the range scale be related in any way to the screen geometry
> (i.e. half-height/half-width)?

So that it is consistent with everyone else. What we are after here is
CONSISTENCY. A METRIC that will be the same for everyone.

>
> The following 2 pictures show the "view" to exactly the same *range* as your
> picture, but to a different "scale".

```
> +-----+
> |RNG      | ZOOM IN

> |LON      + |
> |          |
> |          |
> | |<-----32mi----->|
> +-----+
```

YES, BUT THEN THIS PLOT WILL NOT CONTIAN EVERYTHING WITHIN A 32 MILE RANEG
OF THE CENTER OF THE SCREEN! IF I SAY THAT SOMETHING IS WITHIN 30 MILES
AND I AM ON THE 32 MILE RANGE SCALE, then BY GOSH IT OUTTA BE ON THE DAMN
SCREEN! *** THIS IS EXACLTY THE LUNACY WE ARE TRYING TO AVOID!!!!
This example shows EXACTLY WHY it is HALF-WDITH or HALF-HEIGHT to define
the RANGE SCALE!

```
> +-----+
> |RNG      | ZOOM OUT
> |LAT      |
> |LON      + |
> |          |
```

```

> |                                     |
> |          |<32mi>|                 |
> +-----+

```

I would say that this screen might compute to a range scale of 64 miles.

> This last picture could also be viewed like this:

```

>
> +-----+
> |RNG                                     |      ZOOM OUT, PAN LEFT
> |LAT                                     |
> |LON                                     |      +
> |                                     |
> |                                     |
> |          |<32mi>|                 |
> +-----+

```

NO IT CANNOT. AS SOON AS YOU MOVE THE SCREEN OR ZOOM, THEN IT HAS A NEW CENTER AND RANGE. YOU ARE STILL CONFUSING THIS AS A *** METRIC **** TO DESCRIBE EACH AND EVERY VIEW IN UNAMBIGUOUS CONSISTENT TERMS.

I SAY AGAIN! READ MY LIPS! CENTER AND RANGE DESCRIBE ONLY YOUR PRESENT VIEW! REPEAT THAT BACK TO ME SLOWLY... THINK ABOUT WHAT IT MEANS! IT IS ONLY A METRIC FOR DESCRIBING YOUR PRESENT VIEW IN A CONSISTENT MANNER, DEFINED IN THE APRS STANDARD.

> (i.e. the geographical center is not at the screen center.

Then it is NOT THE CENTER OF THIS VIEW!

> In other words, all of the 4 above screen "views" are *different*, but they
> all represent exactly the *same* geographical area of interest, using the
> *same* range.

FORGET GEOGRAPHICAL AREA OF INTEREST. I HAVE BEEN TELLING YOU THAT THAT CONCEPT IS ALL WRONG NOW FOR 3 DAYS. IT IS THE METRIC for describing YOUR CURRENT VIEW so that you can RELATE IT TO SOMEONE ELSE IN A CONSISTENT MANNER!

> Thus it does not make any sense to talk about your screen "view". You need
> to talk about the *geographical area*, on the ground.

THAT HAS NOTHING TO DO WITH CENTER AND RANGE AS A METRIC TO DESCRIBE A SCREEN VIEW. If you want to define something to do with geography, that is a different subject and totally meaningless in this section..

> >Whereas "my view is on a 32 mile range around Glen Burnie" is MUCH more
> >user friendly.

>
> No problem at all with that, because you didn't use the word "scale", and
> you didn't specify how much of that view occupied your display -- your use
> of the word "view" here does not relate to screen scale or screen geometry.

I certainly did to anyone that understands ENGLISH. My screen contains
**** AT LEAST **** a central area that is 32 miles in range from the
center of Glen Burnie. No one on the planet that understands English can
misinterpret that.

> I repeat: "view" and "scale" are screen/display/window artefacts, associated
> with zoom and pan actions, and are irrelevant to this discussion.

Then you DO NOT UNDERSTAND THE PRESENT DISCUSSION!

> "Center" (=Glen Burnie) and "range" (=32 miles) relate to a geographical
> area, and are directly relevant to this discussion. But anyone using that
> information is free to "view" it and "scale" it any way they want -- this is
> not for the specification to decree.

They may USE MY INFORMATION in any way they see fit! But when I am
looking at a view, I MUST HAVE A METRIC that is *** CONSISTENT *** with
everyone else in APRS to describe it in simplest and concise terms.

Since Ian is so confused about VIEWS and GEOGRAPHY, lets try this explanation.

Lets let everyone in all flavors of APRS, dos, Win,Mac,UIview, APRS+SA whatever display a VIEW that covers EXACTLY the same area. That is everyone's screen displays everything within a 32 mile range of Glen Burnie.

What I want out of this is that when EVERYONE of those users, is ASKED to describe the area he is looking at no matter what software he is using. His SIMPLE, CONCISE description done in accordance with the Standards layed out in the SPEC will all "sound about the Same".

If they DON'T sound the same then we do NOT HAVE A COMMUNICATIONS STANDARD and are only undermining interoperability between all users.

Thanks Roger. I didnt like simplyfing it to just SCALE exactly for the reasons you mention. I agree too that as long as you display a RANGE SCALE NUMBER, you dont have to have the LEGEND. That was only to put it into a context that the people who dont like RANGE circles could in fact use a LINEAR legend and then NOT have to have a RANGE SCALE field along with the LAT/LON...

I think we are in agreement.

Bob

I have assiduously avoided this discussion, because I think the underlying premise is wrong. I do not feel that user-interface issues belong in the protocol document. If they are to be written, they should be done as a separate document. I argue no user interface issues should not be dictated, because it will reflect the status quo, and take away incentive and opportunity for people to innovate.

I get the impression that if Bob could have his way, every program would look exactly like APRSdos, use the same keystroke combinations, the same maps. Yes, as he points out, it would make it easier for anyone to go into an EOC and start using their program regardless of whose version is installed. But is this homogeneity a Good Thing? I say not.

The second APRS program out was MacAPRS, the third javAPRS. Neither of those two have ever had map scale. In the 4 years since I first released javAPRS, I do not recall a single request for this scale legend.

Bob by his own admission is uncomfortable with GUI environments, so his rules would naturally reflect a bias towards the keyboard environment. Even though Mac/WinAPRS does not show a range bar on the screen, it has a far more useful feature, the map caliper. Simply click and drag on a map, and you will see the precise distance displayed. Wanna see how long a mile is? Just drag the caliper out until you see 1 mile displayed.

I especially object to the requirement for a scale legend. By chance the map product I use the most (MapBlast) has this, but I cannot control it, and most other internet products do not contain it, nor is there any way

for me to control most of the parameters Bob considers essential. For example, in the topo maps I can control the scale, but I cannot place a legend on the map, I cannot control the precise center, or even determine what it is.

Besides the underlying OS, the user interface is the thing that makes each program unique. Each program has attracted its accolytes, and their requests have driven the development of the program. Whether to include a scale legend should be up to the program authors, based on input from their users. If it was as important as Bob implies, it ought to be a most-requested feature, and given how easy it would be to implement, it would already be there. That it isn't in WinAPRS speaks volumes for the user's opinion of how important this feature is!

Steve K4HG

Yes, those were the objects. The others looked fine.

NO, but I do expect that EVERY user looking at an area 32 miles around Dayton Hamvention for example on WHATEVER map or MAP system they are using, would all describe that "same" AREA that they see in the SAME way to a 3rd party.

It just amazes me that we have such strong objections to using the word "RANGE" to describe an ENGLISH term that means "an area 32 miles around the Dayton Hamvention".

I just cannot understand how anyone can missinterpret that. The word "around" even derives its meaning from the concept of a circle with a radius of that dimension.

> Yes, as he points out, it would make it easier for anyone to go
> into an EOC and start using their program regardless of whose version is
> installed. But is this homogeneity a Good Thing? I say not.

NO! It allows anyone on any communications channel to "describe" the "size" of what he is LOOKING at on HIS screen in an UNAMBIGUOUS way. It has NOTHING TO DO with what program he is using or how he uses it.

> The second APRS program out was MacAPRS, the third javAPRS. Neither of
> those two have ever had map scale.

And that is their number one failing when used in a cross platform, network of other users trying to communicate what they SEE on their maps. It is this total confusion and inability for a MAC/WIN user to describe what his view to a NON _MAC/WIN user that is driving this issue!

Mac/WinAPRS ALSO DO NOT DEFINE APRS either.

> In the 4 years since I first released javAPRS, I do not recall a single
> request for this scale legend.

I have been asking for it for over 4 years.

> I especially object to the requirement for a scale legend. By chance the
> map product I use the most (MapBlast) has this, but I cannot control it,
> and most other internet products do not contain it...

The failure of the pretty-map-makers to provide meaningful legends or quantifiable scale to the users should not DRIVE the design of APRS nor trap us into furthering this omission.

> nor is there any way for me to control most of the parameters Bob
> considers essential. For example, in the topo maps I can control the
> scale, but I cannot place a legend on the map, I cannot control the
> precise center, or even determine what it is.

You dont understand at all. I am in no way asking for anyone to control anything. I AM ONLY ASKING THAT ALL MAPS DISPLAY TO THE USER A COMMON METRIC that conveys to him the approximate CENTER and "extent" of each MAP view so that THAT user can DESCRIBE it to SOMEONE ELSE in a consistent, concise and unambiguous way that will be understood by all APRS users across all platforms, and all software.

If we AUTHORS cannot agree on a common basis then this is PROOF POSITIVE that our users will be hopelessly confused and be UNABLE to communicate their views across different systems and communications channels.

> Besides the underlying OS, the user interface is the thing that makes
> each program unique. Each program has attracted its accolytes, and their
> requests have driven the development of the program. Whether to include a

> most-requested feature, and given how easy it would be to implement, it
> would already be there. That it isn't in WinAPRS speaks volumes for the
> user's opinion of how important this feature is!

It could also be said that it speaks volumes of why we still have MANY people who are FULLY computer literate, and fully conversant with WIndows and state-of the art in GUI's who still use a CRUDE, OLD and ANTIQUATED program like APRSdos INSTEAD Of WinAPRS.

bob

Nope, these are all garbles..

The objects are all the same packet. Cleary there are bit errors introduced by the "system" somewhere..

I think you didn't understand what I am saying. As a programmer, I have
no control over whether MapBlast, Topozone, or TIGER chooses to implement
something. Therefore you are excluding a bunch of potentially useful
sites and features from the internet system because they do not implement
the features you and a handful of others consider important.
```

Yes, but cannot any application that uses one of these maps also display the center and range of the map, somehow? It does not have to be "on" or "in" the bitmap, it just has to be "associated" with the map view. When I say "legend" I am simply asking for a "note" somewhere, anywhere that conveys to the user the "size" and "location" of the map.

A map without a scale is just a pretty picture...

No, in most cases it is not possible to determine the scale of these
internet maps. So I guess guess you want me to shut the whole thing
down...

I was monitoring A LOT(!!!) of garbage packets, especially on Friday evening. We had a glitched tracker up north in constant keydown sending GPS output in converse mode. The WIDE would break through the mess, but otherwise it was a QRM nightmare.

But given the tremendous collision problem overall, is it possible that somebody who was digipeating had PASSALL turned on? I've never used PASSALL, but I have to wonder if this function will put good checksums on bad packets if they're digi'ed.

...mike

You bet! if any digi anywhere has PASSALL on, it is an absolute disaster,
and you cannot find the culprit! The only way to find it is to build
specific hard-coded DIGI calls, one at a time through all digis in an area
and hope that this way you can slowly but surely identify the bad one.

Yes, the packets will have GOOD CRC's after being digiepated... :-(

Browsing through some IGate output, I see a lot of packets apparently from Kenwood D700s, looking something like this:

```
@242035z0123.45N/01234.56W>291/006/TM-D7/M3/RETURNING]"5#}TM-D700 & GPS-45  
A=000338
```

~~~~~

~~~~~

Is the comment field (following "...291/006") generated automatically?

The encoded altitude "5#}" decodes to 338 feet.

The very last item of data appears to be the same altitude, in plain text.

However, it isn't the altitude, as they omitted the slash before the "A=".

What you are seeing is a Mic-E "converted" packet. We have no idea who converted it, and everyone does it differently to get the embedded control characters though APRSServe as printable ASCII.

I fought this battle over and over with Steve. Remember, I wanted a STANDARD conversion of the Mic-E format by ALL I-gates to a CONSISTENT format. It gave a consistent format for further parsing AND it gave a one BYTE identifier as to WHO's software did the conversion! Thus we had all we needed for CONSISTENT parsing AND future troubleshooting...

Now every author's software converts it DIFFERENTLY before sending it on (in 7 bit printable ASCII) to APRSServe. Thus you have no way of parsing it consistently. Since the ALTITUDE is now added as the first 4 bytes of the STATUS text portion, then where it will be in the Mic-E "converted" format via APRSServe, depends only on which author converted it.

I think this is stupid and will just be a forever problem. I published to ALL authors the recommended standard conversion format. Steve was the big objector to any standardization. Now that he is gone, maybe we can bring this back up and get agreement.

There are now 6 different versions of Mic-E devices transmitting Mic-E and how many different IGate softwares converting them to how many different formats. Let's say 6. Thus we have 36 different possible formats... all for the same information. Darn it, we need a STANDARD!

Needing a "/" before the "A=" is news to me. We've been using "A=aaaaaa" for the altitude display in APRSdos for some time and I didn't know that. Not sure the "/" is needed in APRSdos. Do other flavors use the "A=aaaaaa" for display at all yet? Hope so. Guess I should have read page 25 of the aprs101m.pdf proposal more carefully.

My apologies, I thought I was responding privately to the APRS Working Group. Even so, I always welcomed Steve's opinions, because the ensuing discussions were the only way to hammer out ideas and arrive at what we think is the best way to do things.

He had good points about how hard it was to standardise on the growing plethora of Mic-E implementations and how there was no perfect solution..

This was not intended to denigrate those discussions.
Bob

Actually, I don't like your standard either. Not that it would not work, but it is unnecessary. A simple fix would have been to encode Mic-E packets using an Internet standard such as Base64. And decode it at the IGate. Then you have the ORIGINAL packet, not some cooked up packet. But that has not won any favor either. My proposal was something like this: The converted packet would be CALLSIGN>BASE64:base64_encoded_data_goes here.

Example:

Original packet:

KF6VMM-9>S4PTQR,N6EX-3*,WIDE2-1/1:'-He1R">/]"6o}

Encoded packet on TCP/IP:

KH2Z>BASE64:S0Y2Vk1NLTK+UzRQVFFSLE42RVgtMyosV0lERTItMS8x0ictSGVsUh8+L10iNm99

To decode, you see that the packet is to BASE64, so, take the data portion, and reverse the Base64 and you get:

KF6VMM-9>S4PTQR,N6EX-3*,WIDE2-1/1:'-He1R">/]"6o}

No loss of data. No funky conversion packet. Original data on the Far Side.

What about gating the packet to RF should that be required? Strip out the excess path, and make it a gated packet. Here would be the data portion.

```
}KF6VMM-9>S4PTQR:'-He1R">/] "6o}
```

Brent

I never cared what the format was as long as we had a standard. Your proposal above is not backwards compatible with any existing software. It would require a mod to all user software for anyone looking at the APRServe stream. But since those same software are the basic engines for the IGates, I do think it could be phased in quickly...

So I am not opposed to it. But we just need everyone to implement it in one common manner...

Bob

I'd rather see ONE standard that made sense then a tower of Bable that may result. I've looked at the spec, and in almost every case there appears to be multiple ways to do the same thing. I believe positions can be represented in at least four or five different ways, weather in at least that many ways and who knows what else.

As any programmer knows, trying to write parsing routines for multiple formats is more then trivial. While what's done is done, for the future the WG might consider picking the best format and making that the "must have" standard instead of continuing the dilution of the protocol. ONE standard, not the mish-mash of four+ ways to say the same thing. Just suggest one method, in the spec doc, instead of giving equal footing to all methods.

I like the idea of a base 64 standard as it is "C" friendly and should be able to be implemented on most small microcontrollers. While the compressed format is a nice size reduction, the algorithms needed to convert to it are not very microcontroller friendly (floating point and/or double longs). But I'll take compressed over NEMA any day ;-)

-Jeff

Well, after some simple tests, APRSd does indeed pass 8-bit data, having passed successfully the top 50 ASCII characters in, and getting them back exactly as entered. Thus it appears, that APRSd does not have the APRServe limitation. But we still have a mixed system of APRServe and APRSd. So encoding is still required. My vote would be for a simple Base64 encoding. This will work for APRServe and APRSd. It will also pass the callsign of the originating station, something that is not present currently. Of course, not all packets need encoding. This is what I would propose:

CALLSIGN>BASE64:base64_encoded_data

CALLSIGN is the callsign of the station entering the data to APRServe

BASE64 indicates the data is Base64 encoded
base64_encoded_data is the data in Base64 format

To reverse the process, receiving station detects the fact that the TO field is BASE64. It then takes the data portion of the packet and UNBASE64s it and runs it back through their parser. No data loss. Works with APRServe and APRSd now.

Brent

Actually, I am beginning to like the idea of a standard BINARY to 7 bit
ASCII conversion that will suit ALL applications. All we need to do is
specify an as yet-unused FORMAT character and it simply indicates that ALL
that follows is a converted packet.

Then everyone uses only the one standard DECODE routine to convert it back

to the original packet no matter what it is... End of all problems.

Did your proposal already pick out a FORMAT character?

I like it. Looks good to me!

My idea preserved the original header and so can go over RF too.

But I think yours also is fully AX.25 compliant in KISS mode. Right?

In the below example the only difference would be that there will be DIGI
peater fields. But I think that is consistent with what you designed...

So if thats the case, I think yours wins...

Does anyone else see a problem?

Anywhere? I suppose if you add a digipeater path. But converting a packet to Base64 does increase its length a far bit (pun sort of intended), and the RF network can handle 8-bit. APRServe can not. My suggestion is really for the TCP/IP side. But I'm open to suggestions.

Yep, I agree that it would be verbose, and no obvious need on RF. But I just figured we should not preclude that option. And I think you are saying that it will work there fine (with the digis included). I guess the expansion ratio is 2 bits per byte or about a 25% expansion? Or did I figger that wrong?

I thought that I'd just put a bug in the ear of the folks who are in control of this sort of thing, that -- especially with the discussion of finding an APRS Service frequency on bands other than 2-meters, from a tactical and emergency/safety issue -- it will become imperative that some sort of "band of origination" flag be included in the protocol (even if it is simply added by GATEs during the process of GATE-ing).

Imagine seeing an emergency or health/welfare message coming across a screen and attempting to DF it using conventional DF techniques, not being able to do so because it originated on 10-meters or 6-meters or 440-MHz and was transparently GATED to 2-meters.

I know there are plenty of irons in the fire, this is just a gentle reminder, that's all.

Ev, W2EV

I now realize I was mixing apples and oranges. The above packet is like 3rd party and the entire packet is base64 encoded. But since most of a packet is HEADER which is already all printable, this is somewhat inneffecient.

Im leaning back towards:

SENDER>TOCALL,PATH,PATH:|base_64_encoded data

Where "|" here is a special so-far-unused FORMAT IDENTIFIER that says "take everything following this as base_64 encoded copy of the original packet data field. We would not actually use the "|" character since it is a reserve character, I only used it as an example.

This is completly reversible at the IGATE->RF end...

What do you think?

Bob

Hello,

I just finished reading, in one sitting, the discussions that have resulted from the email "A Question about Map View and Range Scale" from Wed, 10 May 2000.

At the risk of (re)starting something, I wanted to make the following observations:

1) To me, the idea that the range circle is "the largest circle that can fit on the screen" is by definition only a minimal view of what can be seen on a display, since the display's height to width ratio will usually be different between any two users. Usually this should be "good enough" though since it estimates the bulk of what that the other person is seeing, and gaurantees that anything within the defined circle should be on both displays. The unclear parts will be the corners, and the edges perpendicular the the screen's long axis. If it's not clear that something would be in your range circle, then fix it by recentering the circle or changing the range so it will be encompassed.

2) Even if you were to specify a rectangle percicely, that is also not be enough to allow a perfect recreation of a view, esp. if the recreated view will be on a smaller screen, lower resolution display, or with a different aspect ratio.

You will never be able to transfer two views EQUALLY between the following two screens. The top view (below) has extra W/E advantage over the bottom's N/S advantage. A Palm Pilot's display may be able to fit on my home computer's 19" CRT, but never the other way around. Center/Range or Rectangles may only give the receiving station a feel for how big the other user's view is, but that is usually all that is needed. By comparing center and range scale info, two users can at least approximate what the other is seeing and therefore "get on the same page" as it were.

+

+

3) I would describe the difference between Bob's Range Scale and Street Atlas's distance (tick) scale this way:

Bob's range scale is always one-half of the distance along the map's shortest viewable axis.

Street Atlas's tick scale is simply the distance between the two vertical ticks on the |-----| graphic.

Using each requires a different technique: The Range Scale allows me to estimate distances by subdividing an overall number based on visually comparing relative segment lengths (ie: a distance that is about 75% that from the display center to the range circle, and given a 32 mile range scale, is about a 24 mile distance). The Street Atlas tick scale requires a cumulative addition of segments (ie: my index finger width for this particular screen is about one tick, the tick scale may be 0.2 miles, so a distance of about 13 fingers adds up to about 2.6 miles).

An on-screen click and drag caliper between two arbitrary points will always be the most accurate measurement of that distance. And it would be useful for estimating another user's range scale on the local map. But it is a poor tool to use if that is the only way available to generate my range scales for relaying to others, esp. if I am constantly making lots of map zoom changes.

There are at least two advantages of displaying a "Range Scale" value over a

simple "arbitrary scale" value. First, my estimates are probably better, as ~125% of a "range scale" is probably easier to gauge than 14 finger widths times a "tick scale". In addition, the INFORMED/TRAINED user will know a 300% range scale distance refers to a long-axis measurement in an arbitrary window type "display view" and may not be reproducible on a tiny square display. Whereas a 25 unit SA "tick scale" provides no real information of the other user's overall display size, because the SA tick scale has no relation to the overall window size. I just tried resizing an SA display, and a very long and narrow display has the same scale as a square one. A range scale on the other hand would have changed to reflect the screen resizing based on the definition of "one-half of the distance along the map's shortest viewable axis".

4) If the goal is to describe the actual rectangle that the other person is seeing, then add the "missing parameter" that allows one to define the size of that box and to locate it on the map. (Although it still won't help describe the resolution on the map, the amount of map and icon details displayed, etc.)

I personally think that these two methods complement, rather than replace, each other. Voice users will most likely use the center/range construct, whereas fully defined rectangles construct could be used to more precisely transfer view parameters directly between two computers.

5) None of the real-world searches I have been on use computers. There is a great desire by many to change this, but paper will still rule for a very long time to come for a variety of reasons. The center/range metric described by Bob supports paper maps fairly well in two ways.

If a baseline computer view is defined such as the subject's last known point (LKP) with range X, a protractor (or a length of string) can be used to quickly draw an approximation of that screen view onto a paper map. Furthermore, if multiple views are defined/described, then multiple circles (overlapping or not) can be drawn on the paper map and referred to by some predefined area "name" such as the LKP, base area, clue area 1, etc.

Realistically, I doubt that drawing these circles would actually occur. More likely it would be done mentally. One method I like is to spread two fingers apart by the desired distance (Range Scale in this case) and going through the physical motion of drawing a circle as though I was using a protractor while mentally noting the area I was encompassing. Note, this works just as well on a computer screen as it does on a paper map.

The center/range construct's _main_ purpose is to allow someone to express what general coverage area they are seeing. This allows another person to construct some type of gauge for _their_own_use_, either by plotting a

circle on their map, zooming and panning to recreate a similiar screen view, or possbily figuring out mentally what the first person is talking based only on their familiarity with the area.

In the wonferful future to come, a large screen display (videowall :-) map could show the areas that multiple individual user workstations are concentrating on by showing their multiple center/range cirllces on the overall tactical map, and could capture those icons that are out of range of all of the "myoptic" operators. Once glance on the main tactical map could be the alert to focus attention on an area using a different computer's display. The tactical map would, amoung other things, help summarize where your operators are focusing their attention.

6) Mabye I should have spoken up long before, but the lack of any type of scale on applications like javAPRS has been a problem for me. Currently I just make very rough estimates on distances based solely on visual cues from the map itself and inherent knowledge of distances displayed. For example, the displayed distance between the DC and Baltimore beltways, or from the DC Beltway to the I-81 and I-66 intersection. This is fine for rough estimation, but stinks for getting details like how far are we from Manassas VA? With practice, I can now get fair results, but when I show others the types of maps I get the familiar blank-stare as they rarely know what they are looking for/at.

I agree that if a wonderful map site cannot allow you the control (or know) the map scale, or will not allow you to place icons and objects on the output which is to the specs satisfaction, then don't worry about it. If the remaining information does convey what the users think is useful, then it will be used anyhow. But that should not stop the spec from the range scale (or whatever) simply because you cannot implement it given a particular application quirk.

7) Finally, and most importantly, map reading and map usage itself is a skill. I would say that most people are not very good at it. Even experts can get tripped up by various concepts because they may never have used that concept before, or have only used it in a limited way, or don't use it enough to be proficient, or may simply know it may another name.

For example, a "plotting" operator located at a stationary site who is reporting and controlling things around them will probably use different skills and techniques compared to the "navigator" operator who is interested in getting their moving vehicle from one place to another without incident.

The example of how the many different skilled users having never heard of a "range scale" is not suprising to me. They may simply not know what it is, or what good it can do for them, or may have ever needed it, or just don't

recognize it by that name. That does not mean that it is not a useful tool/skill to know. I wonder how many might actually find it helpful once they were 1) taught was it was, and 2) were given the tools that would make it easy to use?

Ask that same group of people how to account for magnetic declination when doing compass work. I have seen people who are experts with map and compass "lose it" during a theoretical-type teaching discussion because what they are used to doing is not always well explained. Furthermore, I know two completely different techniques that both work, but are not compatible with each other. This may be part of the problem with discussing range circles vs. area rectangles.

Finally, I believe there was a sentiment expressed that much of this conversation was a disagreement in underlying technology. I disagree. I think the problem is the fundamental differences of how two people can describe their perceptions of the same thing differently. Two people will probably never agree 100% on what a map display is showing. Even if both were looking at the same size screen, differences in their training, experiences, interpretation, and even eyesight will create different perceptions. The best we can hope for is to minimize those differences, not eliminate them.

^^^^^^

[snip]

Isn't the whole point that "should" is "will"? At least in terms of the geographical area covered. (Or have I misunderstood it?)

Very good summary. I think I agree with everything you have said. And it describes in detail the nuances behind what I am trying to do. I have been hesitant to use so many words, fearing that no one would read it all, but you have summarized it quite well.

Yep, thats all I am trying to accomplish..
and the following is exactly why I cant work with "tiny-tick" scales.
I think the EYE can much better estimate the length of something small
compared to a long legend (visual division) than estimating somthing big
relative to a small legend (visual multiplication).

This really came home to me when someone sent me a MAP from Sout Africa asking me a detailed question about setting up Digipeaters. It was a beautiful color map comparable to any currently availabe map product. It showed 3 Digipeaters and callsigns. But I was absolutely clueless as to whether the digis were 5 miles apart or 50 miles apart! Being TOTALLY ignorant of the geography of South AFrica, I had NO visual clues. THIS incident CONVINCED me of the PROBLEM and that we MUST have a standard for conveyin MAP SCALE.

Remember 4 out of 10 American adults cannot even find the USA on a world map!!!!!!

And I thought when you REQUEST the map, that the URL contains the scale you are requesting? Thus you shuld konw the scale of what you get back.

Wow.

This was very well thought out and well expressed.

The issue of gross differences between display resolution (as with a CRT vs Palm) is an important contribution.

No misunderstanding, "will" is the right word.

Given the amount of time it took to write and edit that email, if that is my
only mistake I must be on a roll.

I believe I was thinking to myself at that moment "reported APRS objects
will be within the circle, whereas map details should be about the same -
assuming an approximately equal representation of base map details by both
users on each of their displays." All of that just came out as "should be".

Darrell

I'd like to learn about how one goes about compressing information in such a way as it (the resulting compressing information) remains a printable ASCII character. I don't know the key words to search on in order to do an internet search engine search. I tried "huffman encoding" but I think that could generate non printable characters.

Is someone in a position to point me in a direction in which I could further my quest, please?

Ev, W2EV

I don't think this is possible.
You can compress ASCII by turning it into sixels, but the result is binary.
You can huffman encode, but the result is binary.
Etc..

You can represent a binary byte in hex, as FF for example, but that takes
two bytes to do, and you've lost any compression you're likely to have
gained.

Hi Dave,
Thanks for the reply. Your insight has given me more of a chance to
think about it more deeply. As it turns out, I may have used the wrong
term ("compression"), when I meant to use the term "encoding". (I'm
learning, though) :o)

I'm going to go on a search engine search on that term to see what comes
up. I seem to remember that UUEncoding allows normally non-transferable
information to become transferable because it is converted to ASCII.
I'm going to pursue that avenue for a while.

Your reply helped to focus me a bit more. Thanks for taking the time!
Warmly,
Ev, W2EV

The only type of compression I can think of that would have a chance to do this is a dictionary type search where one of more ASCII symbols would represent a larger chunk of data. But the conditions to make that happen are usually very prohibitive.

For example, replacing the word "the" with the symbol "*t" or the phrase "in my humble opinion" with the symbol "*IMHO" may get dome compression in a

whole paragraph of text. But noticable gains usually only happens when most of the text is the same repetitive words or phrases, and control characters such as the *, which in this example represents the start of a symbol, can never appear in the regular text.

>I don't know the key words to search on in
>order to do an internet search engine search. I tried "huffman
>encoding" but I think that could generate non printable characters.

Data encoding is such a huge field that I doubt a search engine will be of help much. Some PhD level researchers spend all of their time working on just compression algorithms, so summing up what they do in a few words will be hard. Data encoding by definition is the balancing act done between many variables, and managing the tradeoffs that have to occur while developing any particular algorithm.

Darrell Hale

Well, if it's not compression that you want, then you can convert to hex at
2 bytes/char.

You only use 0-9 and A-F in ascii, and two chars represent any byte. 00 - FF
I'm sure there are other schemes, but probably not so simple to implement.
Look at half a byte, lookup table, output, look at other half, lookup,
output...

Greetings -

Base91 is one rather simple scheme. Check with the APRS Protocol Standard. I think that this is the method used by the packet BBS mail-forwarding system (ie, WORLI, MSYS, et al).

The "UU" system (UUEncode, UUDecode) used on internet is an example of a process for encoding purely binary data into printable ASCII characters for text-oriented transport media. So is BinHex. And, I am sure that there are others.

Dale,

I'm glad you asked. You are in the drivers seat now, so since we never could get all the authors to agree to a standard format, I now agree with Brent. We should convert ALL mic-E packets to base 64 transparently.

I propose that we choose a new unused FORMAT character. That signals ALL software everywhere that EVERYTHING that follows in that packet is BASE64. It is then back converted to ORIGINAL form at the other end. Not only does this solve the Mic-E problem, but gives us a good transparent mechanism in the future... AND it can work with all packets.

Problem is, ALL IGATE authors must implement it... I even chose the leading FORMAT identifier character, but darned if I can find the message now ... :-(

I do not feel we should use one of the last remaining characters for this. There simply is no need, all the data can be converted to other standard formats.

If it is any help- the "." (period) was reserved for automatic space wx packets- I ended up putting space wx in with the rest of the wx stuff. So I don't need it.

There are a number of characters still available. And there are a number of simple solutions if we are about to run out. The main problem is APRServe and Mic-E at this time. And there are as many ways that Mic-E data is converted as there are programs. Currently, APRSd is munging Mic-E data sending positions all over the world. Also, since there are several different conversions, APRServe/APRSd do not see them as duplicates and passes them on. If the packet was encoded, it might not fix the dupe problem, but in the end each client program will see the original Mic-E packet.

> standard formats.

That is exactly the current problem steve!

You wont agree to a "standard" format. So everyone does it diffeerntly,
so there is nothing to consistently check for DUPLICATE or LOOPED packets.
Its a total mess. If the PACKET that I get here, can be ANY of 6
different formats depending TOTALLY on who's Igate software converted it
to HIS perferred "standard" format, then we have a KLUDGE of monstrous
proportions.

EVEN the RF recepiant software at the other end will not recognize the
DUPES coming in from multiple IGates. They will ALL LOOK DIFFERENT, yet
it was the SAME original MIC-E packet at the source. This is CRAZY!

- 1) We need a transparent way to transport Binary packets.
- 2) It should not be restricted to Mic-E packets only
- 3) We should use a common format such as BASE-64
- 4) and EVERY IGATE shuold do it the same way.

First of all, you guys forget there are a half-dozen IGates that are
stupid. Bob's is one. It is just a serial port, and can never convert
anything. So any attempt to produce a software solution that "EVERY
IGATE" (emphasis Bob's, and quite ironic at that) must implement is
doomed.

The majority of the dup problem is caused by the combination of TSB
sending both the original Mic-E packet and the converted one, they have
been promising to fix it for some time. If something is broken in the
aprsd conversion, fix it, that's the point of open source!

This is way over-engineering the problem...

If all Igates do the same conversion to base64 the same way, then the converted packets would all look alike too and thus the dupe filter would get them too.

When a packet is converted, the original then is destroyed and not injected into APRSd...

First of all, I thought mine died over a year ago? I never looked at it
since. It is still on line, then this is good news!

Second, if we will agree on a conversion, I would immediately put in a PC
to do the conversion..

> The majority of the dup problem is caused by the combination of TSB

But then you still have 3 or more other different conversions going on.
And EVERYON's software EVERYWHERE is now then required to recognize these
and any new ones that new authors choose. It is a forever nightmare
until we standardize on one conversion.

> This is way over-engineering the problem...

Huh? Good engineering would agree on one standard, and not keep
bandaiding such a mess...

Steve,

Could you offer some constructive suggestions to solve the problem? You indicate that you haven't been looking at what the network has been doing. If you have the time to do so, I think you will soon agree that the Internet feed contains a considerable number of bad, or malformed packets.

This also affects FindU.Com since it is storing these same bad or malformed packets.

If I look at the stations closest to KC9XG-14 with FindU I see calls such as :
WF6FH#14, =4148.03N/,}N9PN0-1,KG9D@

If I look at stations closest to K4HG with FindU I see :W7IUC--11,W7IUC-,Digi

These have nothing to do with the problem at hand. These are caused by
people sending garbage to the internet system. I have heard people

complain that the problem is PASSALL, but I do not think so. Most likely some program mangles the data and returns it to the feed. My plate is full, I do not have the time to track this down. Dale has added a new feature to aprsd that shows the source of all packets when connected to a special port. I am supposed to get a copy of this new version in the near future, and once it is up at aprs.net perhaps someone can use it to see where the bad data is coming from. I think I have made it pretty clear I am not accepting responsibility for the internet feed. Tracking stuff like this was taking all my time, and I don't, and won't, do it any longer.

Better detection and removal of these bad packets is another thing high on the list for findu, now that I am a "Master of the Regular Expression", thanks to the Perl Whirl, should be a piece of cake!

Here is a simple study of data over the last hour of you type of packet, the

@ packet. Notice the mangled data portions of the packet. APRSd is my suspected culprit here with the Mic-E conversion.

Hard to place the blame on aprsd, as weather packets, messages, and other things get mangled as well. For example, the W7IUC--11 Bill mentions is a stand-alone weather station beaconing a ! position, not a Mic-E packet.

W7IUC--11>RS,WIDE,WIDE,KD4BBM-6*/V:!2440.16N/08121.63W_Big Pine Key FL -WX

Here's a message packet:

H5!.0-15>WIDE,0N58_N,WB4%PH-5,NOT[I-8,Y@M,&N-4*-11,41X#-8KF4FFN,APR823,W2GF
F-7,KU4LY-7*::WA4MTG :hello there{0

Something else is going on...

No matter how minor they are, each and every one of them must be documented, recognized and parsed so that the DUPE ELIMINATOR will work. As it is, none of this is documented nor agreed, since you insisted that APRServe processing not be included in the APRS SPEC. I don't write Igate code, but if you asked me which I would rather do:

- 1) Do dupe checking on any number of conversions, none adhering to any kind of spec that I would have to figure out on my own and modify every time someone changed theirs or a bug was found...

OR

- 2) Agree to one base-64 universal/transparent conversion that would handle all present and future binary packets

I know which one I would choose...

I was looking at a single packet type. Not all. Just trying to figure out what is happening. I suspect more than one. But APRSd is mangling some Mic-E packets. I think that is clear.

Brent

Yes, on reflection, there probably **is** something wrong here. I don't believe this guy was 48 deg **south**.

BTW, I have already commented to other stations privately that their reported posits seemed way off. A few days ago, when looking at the world map, I saw a VE in the Atlantic off the SW coast of Ireland, and a K7 in Singapore

This is really serious, and throws the whole APRS concept into question. As Bob/Brent and others have commented elsewhere, we really need a single IGate standard asap.

But before that, we need to find out what is creating this garbage. In particular, what generates "E>dsy"? This seems like a good place to start looking.

There are two lessons here...

On Sun, 11 Jun 2000, Ian Wade wrote:

1) ALL Software should be doing reasonableness filters on moving stations. Even GPS's sometimes send out erroneous data. I found way back in 94 that I had to check for bad data, and ignore. So APRSdos has always ignored instantaneous jumps on moving stations. I think the SPEC should even recommend this if other authors are not doing it already.

> This is really serious, and throws the whole APRS concept into question. As
> Bob/Brent and others have commented elsewhere, we really need a single
> IGate standard asap.

2) The proposal is that any packet that contains binary info will be converted as follows:

- a) The entire data field of the original is base-64 encoded
- b) The encoded packet begins with a "(" and base-64 follows it.
- c) On receipt of a "(" type packet, the process is reversed.

Brent, can you detail the exact steps in base-64 encoding?

Bob

This standard should include a method to test the ability of IGATEs and applications, to correctly decode MicE and compressed positions. Currently, a single Mic-E packet appears to be decoded differently by the various IGATEs. A standard collection of packets could be developed, and distributed to permit applications to determine if they meet the standard for decoding these packets.

The insertion of timestamps in decoded packets should be addressed as well. If multiple IGATEs decode the same packet it is possible for each to insert a different timestamp. Each of the decoded packets will appear unique to dupe checking code. Perhaps timestamps should be assigned by the end user application rather than the IGATEs?

Some applications append identifiers to the end of converted packets, some convert text to uppercase, and some insert other information. The IGATE standard should specify the exact permitted content, and format of converted packets to ensure that dupes can be detected and eliminated.

Headers may contain extraneous information that could cause some applications to incorrectly parse the packet. The standard should detail what IGATEs can include, and what must be excluded.

The proposal should also include provisions to ensure that dupes can be eliminated.

Since everyone is adding their 2p (sorry, I'm now back in the UK and I think I have to add 17.5% VAT to 2p but anyway...)

Its unfortunate that the MIC-E format uses non-printable characters but since it can't be changed either applications should be 8-bit compliant or base-conversion needs to be done so the original data can be returned. I really hope that the future APRS protocol versions start to limit the large number of formats that exist (yes, I know it can't even be talked about until the current version documentation is final).

Are there any TCP servers right now that can't handle 8-bit streams? Could we just look at not converting these packets and letting them go through as intended? APRSD should handle 8-bit just fine and any program that listens to the TNC data stream needs to handle 8-bit anyway to decode those packets.

One day I'll actually get my java igate finished so I can put my money where my mouth is... ;-)

I think it is possible that there is a bug in the Mic-E conversion code
in aprsd, but I really do not think it is doing the packet mangling being
discussed here.

The packets I posted were the Mic-E Conversion packets. That is what I was discussing. Yes, there are other problems. Probably not a single solution. But when I monitor the APRServe/APRSd data stream, some stations just all over the place. and ">dsy" is very prominent in there packets. The obvious mangled NMEA data with dropped or extra characters are easy. Throw them out. The @ packets with incorrect number of digits for Lat or Long are easy, throw them out. But the mis-converted Mic-E data looks like real data. Fix the source. That is what I was saying.

First, the problem is not "8 bit", but rather the non-printing
characters. No line oriented protocol can handle all NPC's transparently,
CR or LF always has special meaning. Other NPCs also carry meaning, and
so may be filtered out.

When I was working on the problem in the past, I wrote a short program to

send these npc's as part of an APRS packet to the server, and they did not get filtered out. However, somewhere along the path they do get filtered. Unless someone wants to spend some time digging into the details to find out exactly where the problem is, letting them pass is not a solution.

So since aprsd is open source, whgy doesn't someone fix it?

What I said was it should not be included in that spec, but rather in a
separate document. Unfortunately the first one took so much out of
everyone that there seems to be little interest in starting another.

There are a few easily fixed problems. First, TSB need to stop sending both the converted packet and the original. This will greatly reduce, if not eliminate the number of Mic-E packets aprsd sees and converts. In turn, this means a whole lot less possibilities for seeing dups.

Second, someone can look at the Mic-E conversion code in aprsd, find out if there really is a bug, and fix it.

Third, if there still are enough dups to worry about (and should only happen when an area is served by multiple IGates of different types) then standardization of the converted packet could be done.

This is not something that I think calls for a new packet type.

Actually, it would be quite simple to create a line oriented protocol that handled all NPCs. Just like AX.25, Garmin's GPS protocol, and many other protocols. It requires an "escape" character and a conversion character. Then any data can be passed. Example: If the new line character, <NL> is the packet end delimiter, and the "escape" character is @, and the conversion character for <NL> was 1, then anytime a <NL> character was encountered, it would be converted to @1, except

at the end of a packet where the <NL> signalled the end of the packet. The escape character is self is encoded, might just be is self doubled. All NPCs would then be encoded in this way. The overhead is actually quite minimal, and all characters that go in, come out as they when it. Completely transparent.

By transparent I meant one that didn't require escape codes. TNC's use
ctrl-v as the escape code by default.

By transparent I mean what you put in one side, you get exactly the same thing out
the other. Ctrl-V does not apply to KISS mode. KISS mode does not need it.

I've been looking through the spec and other associated documentation that I have, and have found no way to issue a mayday or panpan call using APRS. It seems that the receivers will filter out messages unless they are addressed for the specific recipient. Have I missed something here?

That's what BULLETINS are for. They go to everyone.

Send TO: BLN1

MSG: HELP!, Sinking in Pax RIVER...

And everyone will be alerted. If it is a kenwood, or a Mic-E, then jsut
welect the EMERGENCY button...

But bulletins do not have the same force as the Mic-E alarm function. I would propose a simple addition where if you sent a message TO EMERGENCY, it would trigger the same alarms as a Mic-E alarm.

Brent

I agree. Unless someone objects, I see no reason why we cannot do so.
Of course, people will want to TEST this capability.... Should we also
declare, that an EMERGENCY message with the first word of "TEST" should be
ignored by all operators even though the alarms will still occur.

Clearly these will be nuisances, but it is nice to have a plan...?

There really should be a test functionality.
pls don't implement like my SAME radio.. the screeching alarm weekly is a
great way to get the speaker disconnected. Tests should be quiet, and only
generate a "test ok" message.

Ian,

Trying to determine why a D700 won't 'List' any stations in memory.
Downloaded & skimmed thru the spec PDF, but on what page is a listing of
acceptable characters to follow the semicolon? My Kenwood only displays the
call sign with ?? after it and I have never had the freq. display blank to
the other info screen. So little APRS data here in SW Kansas, that I don't
know if the radio is working properly. The only data I have seen (Pmon) had
an ' after the semicolon.

Gun Steele WÿGUN

>an ' after the semicolon.
>

Hi Gun. I'm not sure what you mean by "to follow the semicolon". I
wonder if you mean the colon : . If so, the full list of acceptable
characters is on page 17 of draft version 1.0.1m (30 April 2000) --
"APRS Data Type Identifiers".

The apostrophe ' signifies "Old Mic-E Data", for everything *except* the
D700 -- Kenwood got it wrong, and uses the ' to signify "Current Mic-E
Data" instead.

Other Data Type Identifiers you will most often see from a Kenwood are:

> Status message
: Message
; Object

Hope this helps.

APRS Proposal

I am considering the following capability in my version of APRS. This capability has several parts and some broad implications.

(1) There will be a "reference view" for the map. After a reference view is selected, clicking a button will return you to the same view. The map window will be the same size and the same geographical area will be shown from the same map at the same scale. This is not a big deal.

(2) Whenever a user sets a NEW reference view, a dialog box will appear, asking if this view is to be transmitted as an open-box object. The default is "NO" and the user will have to choose "YES" in order to have it sent.

(3) Such objects originating from a reference view selection will be transmitted with a standard name, perhaps "RefVw#####" (9 characters to

satisfy the naming convention for objects). The 4 "#" characters might represent a sequence number or other info yet to be specified.

Other than concerns of "clogging the channel", such a transmission should be fairly benign. Other APRS stations will interpret it as an area object. It will appear on their maps as a rectangle if the object falls within the boundaries of a map they are using. It will, if I understand the operation of other programs, fade away after a while.

(4) Other users of my software, however, on receiving an area object named "RefVw####" (or what ever its final "standard" name is) will get a dialog box asking whether or not the user want to "adopt" this reference view. If they choose "YES" it becomes their reference view but they transmit nothing (that is, THEY do not begin transmitting an area object). If they choose "NO", then nothing happens. I have not yet decided what to do if the user chooses NO and another transmission of the same view is heard. There WILL be a cautionary alert if they choose YES when there is an existing reference view.

Once adopted, any time they click the "Reference View" button, they will see (approximately) the same view as anyone else who has adopted this reference view. This reference view remains until they change it or Quit the program. The user will be able to scroll away from this view, change maps, etc, but clicking the "Reference View" button will always return them to that view.

There will be differences in map style and resolution, but the same geographical area will be displayed in every case, within the constraints of the square-root of the height and width specification. That is, the originator of the view might have it set to .081 degrees width and everyone else will see at .064 degrees width because the width is transmitted as 08.

It appears that the use of area message also limits the largest view to about 9.8 degrees (99*2 hundredths of a degree).

While this scheme is less than ideal, I have chosen it for several reasons:

- * It should have little negative effect on people who do not use my APRS implementation.
- * It uses existing protocol definitions.
- * It allows experimenting with this idea of automatic transmission of a common reference view, which should be particularly useful for event and SAR situations. It should make it very easy for a new station joining the activity to quickly see what every one else is seeing. No voice coordination is required.

* It allows exploration of methods of dealing with the acknowledged problem of reference views which extend beyond the user's map capability.

* If it proves to be useful, a better suited message type might be developed in later standards documents. These experiments should be useful in determining whether or not it IS useful.

=====

I welcome ideas, suggestions, comments, etc.

I applaud the originality of this idea and have no objections. But the emphasis on "reference" view has nothing to do with the previous discussions of a common requirement to display a "map scale". Having said that, it seems ok to me, though I don't see it being used much. The power of APRS is that EVERY viewer has his own screen and his own ability to zoom anywhere at any time to see anything he wants. He rarely if ever remains on the whole-event-view. He focuses on what is needed at any instant in time. But I think this is a perfect application of the "AREA-BOX" feature in APRS. For whatever its value... So, ok by me.. :-)

=====
ANNOUNCING <APRSdec>TM Version 2.0
THE FULL APRS DECODER PROGRAM
by Ian Wade, G3NRW
16 June 2000
=====

<APRSdec> version 2.0 is now available. <APRSdec> parses APRS packets in TNC/IGate output format or UI-View log format, producing a full decode of every data element in each packet.

<APRSdec> is a particularly useful tool for:

- o APRS software development and testing.
- o PIC development and testing.
- o Network fault-finding and diagnostics.
- o Learning about the APRS protocol.
- o Checking packet formats.

<APRSdec> version 2.0 is a significant enhancement over earlier versions. It has much improved error checking, and for the first time is provided as a Perl 4 source, allowing it to run on most platforms including DOS, Windows and Linux/Unix.

<APRSdec> is made available under GNU General Public License.

<APRSdec> is a trademark owned by Ian Wade, G3NRW.

=====
<APRSdec> FEATURES
=====

- o Runs under native DOS, Win 95/98 and Linux/Unix. (It will almost

certainly run under Windows NT and Windows 2000 as well, but this has not been tested).

- o Accepts raw input in TNC/IGate output format (TNC_header:data).
- o Accepts raw input in UI-View 2-line log format; it is no longer necessary to edit log files before using <APRSdec>. In addition, as well as decoding APRS packets, <APRSdec> also decodes the 15-digit UI-View timestamp.
- o Performs rigorous format checking, with detailed error reporting.
- o Understands position ambiguity, reporting the bounding box in which the station is located.
- o Compares lat/long position against a prefix/country database -- if the station's position appears to be outside the country, <APRSdec> reports a possible anomaly.
- o Reports data values in imperial, nautical and metric units.
- o Fully decodes Mic-E and compressed position formats.
- o Recognizes data from Kenwood TH-D7 and DM-700 radios, and changes the incorrect DM-700 APRS Data Type Identifier to "Current Mic-E Data".
- o Provides detailed weather station reports, including the calculation of windchill and dew point.
- o Decodes storm data.
- o Decodes bearing and range data.
- o Decodes DX Cluster reports, showing the data as it will appear on TH-D7 and DM-700 screens.

```
=====
SOME EXAMPLES OF <APRSdec> OUTPUT
=====
```

A simple lat/long report:

```
-----
Record #170
KE4SZT>APRS,W4NHV-9,WIDE*,WIDE/2:@270700z3408.76N/07924.60W-  John in Marion,
SC-793-
APRS Data Type= Posit w/ time. With APRS
Day= 27  Time= 07 hours 00 mins UTC
```

Lat= 34 deg 08.76 min N Long= 79 deg 24.60 min W
Icon= House QTH VHF Overlay= (none)

A raw Mic-E report. <APRSdec> recognizes this comes from a Kenwood TM-D700 radio and automatically changes the APRS Data Type to "Current Mic-E data":

Record #8051
KC7EQL>VE7VAN-3*>WIDE3-1>T8PWPW:'37]lIe-/]"55}Mark at Home awaits Sunsat
APRS Data Type= Current Mic-E data
Radio= Kenwood TM-D700
Message Type= /M2/In Service
Lat= 48 deg 07.07 min N Long= 123 deg 27.65 min W
Icon= House QTH VHF Overlay= (none)
Course= 173 deg Speed= 4 knots (4.6 mph 7.4 kph 2.1 m/s)
Altitude= 397 feet (121 meters)

A compressed lat/long position, within an Object report:

Record #1763
N9IDH>APRK11,AE9A-10*,WIDE3-2:;A016 _111826z\%H+!JvA!Sk{!
R=05280/437.051/13Khz/APRStk
APRS Data Type= Object
Object Name= 'A016 ' Object Status= Killed
Day= 11 Time= 18 hours 26 mins UTC
Lat= 81 deg 14.20 min N Long= 14 deg 04.30 min W
GPS Fix= Old (last) NMEA Source= Other Compression Origin= Compressed
Course= 296 deg Speed= 1018 knots (1171.5 mph 1885.3 kph 523.7 m/s)
Icon= Satellite/PAC Overlay= (none)

A lat/long report with position ambiguity. The station may be located anywhere inside the bounding box:

Record #121
W9ZGU>APR846,WA4WHD-3*,WIDE/V:=2559. N/08010. W-PHG6560/Carl's Castle!
APRS Data Type= Posit w/o time. With APRS
Ambiguous position. Opposite corners of bounding box:
NW Corner: Lat= 25 deg 59.99 min N Long= 80 deg 10.99 min W
SE Corner: Lat= 25 deg 59.00 min N Long= 80 deg 10.00 min W

Icon= House QTH VHF Overlay= (none)
Power= 36 watts Height above average terrain= 320 feet (97.5 meters)
Gain= 6 dB Range Circle= 41.4 miles (66.6 km) Directivity= Omni-directional

A Maidenhead Locator report. The station may be located anywhere inside the bounding box:

Record #459
CT1DBH-1>ID:[IM58IS]
APRS Data Type= Maidenhead Grid Square
Maidenhead locator bounding box:
 NW Corner: Lat= 38 deg 47.50 min N Long= 9 deg 20 min W
 SE Corner: Lat= 38 deg 45.00 min N Long= 9 deg 15 min W
**NOTE: This Maidenhead format with square brackets is obsolete.

A UI-View report, including the decoded UI-View timestamp.
(This report shows APRS Working Group Chairman John Ackermann, N8UR, jogging towards G3NRW's QTH at over 72mph -- he was on a train at the time! <APRSdec> also recognizes that John is outside the contiguous 48 states, so it questions the reported location):

Record #622
N8UR-7*>RELAY>WIDE>WIDE>WIDE2-2>U1UVXX (UI):`v9f">[/>"58}
UI-View Timestamp= 27 May 2000 12 hrs 58 mins 32 secs (PC clocktime)
APRS Data Type= Current Mic-E data
Radio= Kenwood TH-D7
Message Type= /M2/In Service
Lat= 51 deg 56.88 min N Long= 0 deg 29.74 min W
**QUESTION: Is this lat/long position reasonable?
 It seems a long way from home for this callsign.
Icon= Jogger Overlay= (none)
Course= 1 deg Speed= 63 knots (72.5 mph 116.7 kph 32.4 m/s)
Altitude= 407 feet (124 meters)

A full WX station report, with computed windchill and dewpoint:

Record #5034
KF0ZH*>APR819,GATE,WIDE2-2:@111955z4447.06N/

09329.48W_125/008g009t079r000p003....h41b10190dU2k
APRS Data Type= Posit w/ time. With APRS
Day= 11 Time= 19 hours 55 mins UTC
Lat= 44 deg 47.06 min N Long= 93 deg 29.48 min W
Icon= WX station Overlay= (none)
Wind Direction= 125 deg Speed= 008 knots (9.2 mph 14.8 kph 4.1 m/s)
Gust Speed= 9 mph (14.5 kph 4.0 m/s 7.8 knots)
Temp= 79 degF (26.1 degC) Windchill= 76.5 degF (24.7 degC)

Not to beat a dead horse tooooo much, but has anyone checked that
"mfilter 0" is set as the default in all of the aprs packages,
including the setups for aprsd and such?

I had trouble receiving MIC-E packets at home until I set mfilter to
0. The PK-88 TNC was filtering out the non-printable characters for
me, so those characters never reached my computer. Even "mfilter 0"
could cause problems for some (few) packets, as it will filter out
any 0x00 characters.

Mfilter could be another reason that MIC-E packets are getting corrupted here and there, particularly at igates.

I haven't check though, is mfilter a TAPR-2 command? It's definitely in some AEA TNC's.

If anyone has a better solution (a way to turn of filtering altogether?), please let me know. Yes, I know that KISS mode is the proper solution.

My KPC-3 manual shows a "FILTER" command which removes

control codes \$00 to \$19 (hex) . Since Mic-E only uses 5 unprintable characters, \$1C, \$1D, \$1E, \$1F and \$7F this should not affect it.

The spec also shows that some telemetry bytes may be 0x00 - 0xff,
but I think that was only for beta version MIC-E's? How many of
those might even be around? Probably very few. I haven't looked
at the spec enough to know if there might be other bytes than can
be below 0x20 in some of the other message formats.

The AEA PK-88 manual states the default value for mfilter is
0x80. This will filter out all received control characters
except 0x0a, 0x0d, and 0x09. This means that 0x1c - 0x1f
will disappear. I set my TNC to "mfilter 0", so it'll only
filter out 0x00 bytes.

Anyone running AEA TNC's will have problems decoding MIC-E
packets correctly unless they changes mfilter from the default
value or are running KISS mode. The packets can become
corrupted and then can be relayed corrupted. The symptoms I
was seeing on Xastir with a PK-88 were that positions would
suddenly dart to the left or vertically, then return back on

track after the region of unprintable characters was crossed by the mobile. I still see that happening, but it's not my receiving station that is causing the problem anymore.

I just found an original TAPR2, Rev 2 manual, and it specifies that mfilter has a default of "none" for the TAPR-2. This manual was printed in October of 1985, so the default may be different for newer EPROM's.

I dug out my spec. This is quoted from V1.0 .

2. The objective is to have a net cycle time of 10 minutes for local use. This means that within 10 minutes of arrival on the scene, it is possible to captured the entire tactical picture.
3. All stations, even fixed stations, should beacon their position at the net cycle time rate.

I suggest that users who need to send position updates more frequently consider the impact of doing so. Though it may work fine in some uncrowded areas, it may cause interference in other areas. It may be advisable to use a private frequency, so as not to interfere with others.

I think this depends on what the tracker is doing and where he is at.. 10 minutes at 60/75 miles an hour???
At that speed @ 1 minute he would be outta your hair in 10 minutes, or you wouldn't have even known he was there!! :-) IMHO

I didn't write the spec. I assume that they did an analysis to determine what kind of data rate the protocol will handle and based their net cycle recommendation on that figure. I use their recommendation to set my transmit interval to 10 minutes. If running at a significantly higher data rate interferes with the operation of the net, then (the way I read it) you

are in violation of FCC regulations. Though you could probably listen to the frequency and get a good idea how busy it is running in your local area, you probably can't determine how far your repeated signal is being transmitted. I doubt that you could determine if running a faster net cycle would cause interference. If you really need a higher update rate, then you are using the protocol for more than its intended purpose. Switching to a private frequency for that purpose sounds like the proper thing to do.

Kenwood set the default cycle time to 3-minutes. I find this odd, since it appears to violate the spec. Is everyone running at a 3-minute rep-rate?

Perhaps someone from the APRS Spec group could provide their comments?

Sorry, folks, but I have to speak up on this one.

Richard Carter wrote:

> 2. The objective is to have a net cycle time of 10 minutes for local use.
> This
> means that within 10 minutes of arrival on the scene, it is possible to
> captured the entire tactical picture.
> 3. All stations, even fixed stations, should beacon their position at the
> net
> cycle time rate.

Omigosh. Are you serious? This is surely NOT addressing GPS mobiles. Otherwise, what's the point? Why even have a tracker if someone won't even see you as you pass through their city?

> I suggest that users who need to send position updates more frequently
> consider the impact of doing so. Though it may work fine in some
uncrowded
> areas, it may cause interference in other areas.

It is most advisable only to transmit when there is something that has changed. Your house doesn't move, so it should beacon at the net cycle

rate. Timed rate beaconing for mobiles sends information at the wrong time, yielding excessive "spam" and a poor track at the same time. Corner-pegging and distance-pegging are a much better way, but unfortunately very few APRS versions/devices currently support them (APRS+SA, HamHUD).

> It may be advisable to use
> a private frequency, so as not to interfere with others.

I hope this sentiment is not heeded by others, because it will 1) fragment the APRS network, and 2) render precious assets such as digipeters and IGATEs unusable.

APRS FD ops,

The minimum number of packets required to support just 20 APRS Field Day contacts can be from 400 to over 2000. Each station having to send a QSL to every other station (including up to 5 retries each).. Obviously this is a waste of bandwidth. This FD, I experimented with an auto-APRS-FD mode where my station combined all QSL information into one or more re-usable BULLETIN packets:

BLN1CQFD :QSL 3A-MDC,W3ABC,N0KT,KC5ION,KC8UZ,WB4APR,N3KTP,N8DEU,K2SAT
BLN2CQFD :QSL 3A-MDC,N4ZQ,K4RS,KC8MZM,W8UC,N5ZNL,KC8KZM

Here the BULLETIN numbers are the 1 & 2 characters. By bundling the QSL calls in one bulletin, you improve the chances that the other stations copy it while minimizing QRM. Once it is full, then move onto BLN2CQFD. Then the decaying algorithm for APRS will concentrate on the older bulletin less and less, and place priority on the new BLN2CQFD bulletin.

DETAILS:

1. Put your FD exchange in your POSIT comment 3A-MDC for example
2. For each new station seen:
 - * Add the callsign to a single "QSL" BULLETIN line to REPLACE your previous QSL bulletin. ERASE the previous packet.
 - * If one line fills up, then move to next BLN#CQFD. The full BLN#CQFD line decays as usual to lower and lower transmit rates.

EXAMPLE:

After 1st stn BLN1CQFD :QSL 3A-MDC,W3ABC
after 2nd stn BLN1CQFD :QSL 3A-MDC,W3ABC,W4XYZ
after 3rd stn BLN1CQFD :QSL 3A-MDC,W3ABC,W4XYZ,W3XYZ,W5HIJ
etc BLN1CQFD :QSL 3A-MDC,W3ABC,W4XYZ,W3XYZ,W5HIJ,WB4APR,W3STL

In APRSdos, the actual Key strokes to COPY a message and add to the end are as follows:

```
S,<,#,XXXXXX  
E,#
```

Where S is for SEND, <(ENTER KEY), is to RESEND the same TOCALL (BLN1), # is the line number of the previous line, and XXXXX is the new call for the end. Then E is to erase the previous copy of the old Bulletin.

Thus, your station is never sending more than a single packet, yet that single packet is not only serving to QSL up to 8 stations at a time, it is also calling CQ and including YOUR FD exchange for everyone else.

Quite efficient. In fact, MY station was fully automatic. It did all of this unattended. It looked for any NEW station, checked to make sure it was an APRS-MESSAGE capable station (not a DIGI, WX station, or TRACKER or many others) and then added it to the BULLETIN.

For next year, I will make the above filter even more exclusive and have it ONLY try to QSL other "HUMAN" stations. Turns out, there are LOTS of APRS stations with the "lights-on, but nobody's home". To minimize QRM, I want the algorithm to ONLY try to QSL other APRS Field Day stations. This is why the BLN#CQFD includes the BULLETIN GROUP of "CQFD" so that the auto-QSO software at the other end will know to QSL back...

SCORING. According to the "lawyers", under this algorithm, if you SEE your call in anyone elses QSL Bulletin, it counts (assuming all of your outgoing packets contain your FD exchange). That is why I included the FD Exchange in the BULLETIN too.

SUMMARY. With this APRS-FD Algorithm, the number of Packets on the air for 20 stations is reduced from 400/1200 down to a minimum of 20. Yes, those 20 packets are repeated, but due to the decaying-algorithm of APRS, they fade out of the system. Just think in terms of every station on the air for FD is just repeating ONE packet. Thats no worse than NORMAL! yet it accomplishes the OBJECTIVE...

de WB4APR, Bob

As I ready a new release of aprsd, I want to make sure I have the Mic-E converter code implimented correctly. There are differences in the way latitude is encoded in two spec documents. The "APRS Mic Encoder Message Formats" from 1997 by Alan Crosswell indicates the latitude is directly encoded in the low nibble of the ax25 destination address
eg: xxx0001 = lat digit 1
Alans Mic-E converter code simply ANDs the byte with 0x0F and prints the result as a number, 0..15, and assumes only 0..9 will actually be used.

So, Ascii "1", 0x31 = lat digit 1
and also ASCII "A", 0x41 = lat digit 1
and ASCII "Q", 0x51 = lat digit 1
Unfortunately, ASCII "Z", 0x5A = lat digit 10

The new APRS Spec requires a lookup table.
example:

ASCII "1", 0x31 = lat digit 1
ASCII "A", 0x41 = lat digit 0
ASCII "Q", 0x51 = lat digit 1
And, via table lookup, ASCII "Z", 0x5A = lat digit "SPACE"

Will someone verify that the table on page 42 of the APRS Spec is indeed correct and superceeds the information in the Alan Crosswell document.

Hi Dale. Alan's doc is very definitely incorrect.

In article <LYR14779-93051-2000.06.26-10.23.49--Ian.Wade@care4free.net@lists.tapr.org>, Dale Heatherington <dale@wa4dsy.net> writes

>

>
>So, Ascii "1", 0x31 = lat digit 1

>and also ASCII "A", 0x41 = lat digit 1

This is where it falls down. It contradicts his table of latitude/ASCII characters, where "A" is shown to mean lat digit "0". Nobody spotted this before, because the original Mic-E units did not support Custom messages.

>and ASCII "Q", 0x51 = lat digit 1
>Unfortunately, ASCII "Z", 0x5A = lat digit 10

And this is what caused all the confusion recently over position ambiguity!

>
>The new APRS Spec requires a lookup table.

It doesn't actually *require* a lookup table. I intentionally introduced a lookup table because of all the confusion in Alan's doc, to purge from peoples' minds the idea that the least significant nibble always equates to the latitude digit. You obviously can still implement it by masking the least significant nibble, but you have to remember to subtract 1 if the letter is in the range A-J, and you have to remember to handle the position ambiguity characters K, L and Z specially. If you look at <APRSdec>, you'll see that the use of a table makes it bombproof, and faster.

>example:
>ASCII "1", 0x31 = lat digit 1
>ASCII "A", 0x41 = lat digit 0
>ASCII "Q", 0x51 = lat digit 1
>And, via table lookup, ASCII "Z", 0x5A = lat digit "SPACE"
>
>Will someone verify that the table on page 42 of the APRS Spec is indeed
>correct and superceeds the information in the Alan Crosswell document.
>

All of this caused me a lot of pain in verifying that the latest spec is correct. I have checked *many* live reports from IGate logs, and also from local on-air packets, to verify that the table in the latest spec is correct.

P.S. Alan's doc is also wrong in the table of latitude/ASCII characters, in that the headings on the "Message/N/W/L Bit=0" and "Message/N/W/L Bit=1" columns are transposed. This caused me a *big* headache when I started looking into this. Again, extensive checking of on-air packets proved that the table headings were indeed the wrong way round.

What has happen to the APRServe Network - Southern Florida (aprs.net 10151). Yesterday afternoon it seemed to go down and I have not been able to connect since. The only site I can TCP too is WD4DSY in Atlanta.

What options currently exist for authentication?

I'd like a program that I'm writing to cooperate with other software (like aprsd). I'd rather not call an external module for authentication, but I believe some of the APRS programs out there do just that.

This program is written in Perl 5 if that makes a difference. I don't care about license authentication, just authentication to gate the user's packets to RF.

Hi to all,

I'm part fo the VE2ETS club in Montreal, and help maintain the IGATE in Montreal. The club has had a weather station project for about a year now and is near completion. Note that it is a homebrew station that will get acquisition on a PC. Since APRS supports weather information, I Thought that it would be nice to post the information to APRS.

I'm also in a project to help with the aprsd program (as some may already know). After looking the weather section in the APRSSPEC document available on the TAPR site (needed for the proect), I found that in the weather packet, their is one bit for the source of the information, i.e. Win/MacAPRS and other choice, but I failed to find an IGATE as a possible source.

Few Question :

More than a year ago I started injecting weather data into aprs
and ran into the same problem. My weather station is completely
home made and the software is a mixture of custom Java pgm doing the data
collection
and aprsd doing the aprs data communication.
I just used "L" for the software type (L=Linux) and "dsy" (last 3 letters of my
call)
for the weather station. No one has complained so far.

Maybe there needs to be an official code for "custom made" weather station
hardware and software.

Perhaps, we could just append a checksum on all APRS packets. With Position and Status packets, appending a NMEA style "*XX" would not affect older programs ability to see the packets. Message packets might be a problem, perhaps, add it to the text portion of the packet, before the message number and reply/ack. I'd bet weather and telemetry would work with older programs.

The status packet:

```
>111325z[199YD]APRS is "RAD"IO
```

would be come

```
>111325z[199YD]APRS is "RAD"IO*30
```

Message packet:

```
WB4APR :Test message{01}
```

to

```
WB4APR :Test message*05{01}
```

The checksum including everything but the message numbers.

It would offer some assurance of validity to the received packet. Something that is currently lacking in the APRS protocol.

Brent

I agree 100%. Presently, the integrity of data on the Internet feed is questionable. Mangled packets abound. One of the primary advantages of your

proposal would be greatly simplified dupe checking. Checksums could be optional and handled in much the same manner as NMEA packets.

Why couldn't a checksum be added after the message number or ack in messages?

Bill KC9XG

But the problem is where do you add the checksum?

If at the transmitter, that means all D7's, D700's, Mic-E's and stand
alone (NMEA) trackers need firmware upgrades. And who cares about
compatibility with old software, they all would need to upgrade or their
data would be lost.

If you do it at the IGates, it doesn't solve the problem. All the
instances I tracked down were occuring within or before an IGate. So the
bad packets have a good checksum appended to them by the IGates.

Adding it ANYWHERE would be a start. Bit errors can occur at all stages. Let's attack it where we can. This certainly sounds like a good candidate for a "recommended" option for the 2nd version of the protocol.

How about a CRC-16 checksum (or better) instead of the NMEA-style. Better at catching certain types of errors. Making it optional is good. We could migrate to the new system over a period of years.

I haven't a clue how to shoehorn it into the current protocol. I certainly wouldn't mind burning new firmware for my systems to get checksums added.

Here is some data taken from the Internet feed today.

KB2WQM-9>APK001:@151441z3911.00N/07444.93W[000/000/Mic-E/M4/Committed>kb2wqm@amsat.org

KB2WQM-9>3YQQ0Q: `fHz1 Å[/>kb2wqm@amsat.org

KB2WQM-9>APRS:@151338z3911.00N>07444.93W/063/000/Mic-E/M4/Committed>kb2wqm@a

msat.org

KB2WQM-9>APRS:@151337z3911.01N/07444.94W[000/000/T>dsy/M4/Committed.
kb2wqm@amsat.org

KB2WQM-9>APK:@151337z3911.01N/07444.94W[000/000/TH-D7/M4/COMMITTED>kb2wqm@amsat.org

NOTE: There are 4 separate conversions. 2 by WinAPRS, 1 by APRS+SA and 1 by APRSD. The Mic-E packet is shown, but probably is not faithfully reproduced by my Email program.

Packet 1: WinAPRS. The to field is APK001. This is true even for D700 radios which use APK101. The origin is stated to be Mic-E, but in fact, is TH-D7, a Mic-E variant. The time is way off compared to the other packets below

Packet 2: The Mic-E packet.

Packet 3: Origin? I suspect winAPRS. Note that the Icon is encoded incorrectly.

Packet 4: APRSD conversion. The origin is stated to be T>dsy. Was it TH-D7 or TM-D7? This is lost. Icon is OK.

Packet 5: This was converted by APRS+SA. TO field is APK, meaning Kenwood. The origin is the TH-D7. Icon is OK, Lat/Long agree with APRSD. Even the TIME was the same.

This is an impossible situation to remove duplicates. Lat/Long are different by .01 minute. Not significant when plotting on a map, but hard to figure out when removing duplicates. TIME, while packet 1 has reasonable Lat/Long and correct Icon, the time is vastly different than packets 3,4 and 5. Packets 3 is just plain fubar with respect to Icon. Packets 4 and 5 agree very closely. But deduping? Arrgh.

Conclusions:

Mic-E data is all messed up. Clearly, converting Mic-E to a "standard" APRS packet is not working. One solution is converting the Internet side to APRSD. This could be a hardship for Mac owners running APRServe. This would still require that ALL client programs be updated to remove the Mic-E conversion code. What should be done???

Since so many program exist, it's pretty hard to get every body on the same foot to dance...

In my opinion, any "presentation" program (program taht presents the packet on a map graphically) that can connect both on a serial port for RF info and onto the internet, should be the one to convert the packets, which they already do.

The IGATE should only be there to pass information that they hear on the RF (whichever way to listen) and render these packet onto the internet for other to come and get. Even if the IGATE keeps the conversion capabilities, onely one side of the fence should do it.

When this is done, packet dups whould be reduced, on the internet side anyway... Also an important point is to get the proper "standard" implemented in whichever program so that no confusion occurs.

Once again it is time to start planning for the APRS Symposium at the
Digital Communication Conference. It will be held Friday, Sept 22, 2000
in Orlando. More info on the conference is available at

<http://www.tapr.org/dcc>

This is as close as APRS comes to a national convention, past years have
drawn most of the movers and shakers within APRS. If you love APRS,
you'll love the Symposium!

The APRS Symposium will run roughly from 1PM to 7PM, exact times to be
determined. Undoubtably the usual suspects will be presenting, but I
especially want to encourage people that haven't presented before to do
so.

Anyone (including the usual suspects, I will not chase you down this

year) that will be there and wishes to present should notify me within the next week, including the topics you wish to present and the amount of time you would like.

If you aren't going to DCC but have something to share, consider submitting it for publication in the proceedings anyway, it is a good way to get information published. Deadline is August 7, details on submission are available at the above DCC web site.

See you there!

Steve K4HG

G'Day All,

Simple question on intnetnet gating: Should packets that have been forwarded from the internet to RF ever be forwarded back to the internet?

For Example

VK2TDS -> INTERNET -> VK2HDJ -> RF -> VK2XGJ -> INTERNET

Should this never happen... It would make network design much easier

Darryl

No, but even if they are they are filtered out by aprsd and APRServe.

Press Release: July 6th, 2000

19th Annual ARRL and TAPR Digital Communications Conference

2000 ARRL and TAPR Digital Communications Conference
September 22-24, 2000
Orlando, Florida

It is that time again! Time to start making your travel plans and thinking about what to publish for the upcoming 19th Annual ARRL and TAPR Digital Communications Conference.

The ARRL and TAPR Digital Communications Conference is an international

forum for radio amateurs in digital communications, networking, and related technologies to meet, publish their work, and present new ideas and techniques for discussion. Presenters and attendees will have the opportunity to exchange ideas and learn about recent hardware and software advances, theories, experimental results, and practical applications. The Digital Communications Conference is not just for the digital expert, but for digitally-oriented amateurs of all levels of experience.

The 2000 ARRL and TAPR Digital Communications Conference will be held September 22-24, 2000 in Orlando, Florida. This year's conference location is just minutes away from the Orlando International Airport (MCO).

Not only is the Digital Communications Conference technically stimulating, it is a weekend of fun for all who have more than a casual interest in any of the ham digital communications modes. This includes networkers, sysops, software writers, modem designers, and digital satellite communications enthusiasts. The ARRL and TAPR Digital Communications Conference is for all levels of digital operators -- a must conference to attend to get active on a national level. Now, more than ever, amateur radio needs this great meeting of the minds, since it is important that we demonstrate a continued need for the frequency allocations we now have by pushing forward and documenting our achievements. The ARRL and TAPR Digital Communications Conference is one of the few ways to record our accomplishments and challenge each other to do more.

Area Attractions

The Orlando Florida area is famous for its attractions and vacation spots.† Disney World, Universal Studios, and Sea World (just to name a few) are within 15 minutes of the hotel. Shuttle service from the hotel will be available for a small fee. Cape Canaveral and Cocoa Beach are a 30 minute drive East of the hotel.

>me within the next week, including the topics you wish to present
>and the amount of time you would like.

So far, with half the week gone, I have gotten requests from only these people:

The Sproul Brothers
John Hansen
Tom Schaefer
John Blowsky
Darryl Smith

If you are going to be at the DCC and wish to talk at the APRS symposium, you must let me know in the next few days. Please include the topic and the length of time you would like.

APRS AUTHORS TAKE NOTE

I am not chasing people down, if I don't hear from you by Sunday I will presume you do not wish to present. There are simply too many authors now for me to do this individually...

Everyone else take note

I'd love to see more of you presenting!

Thanks,

Steve K4HG

I don't understand this, you say your not suggesting using PSK31 for APRS
yet your saying you interpret FM18SX as a grid square and plot it. The
implication here is you plot on a computer map.... or are you just suggesting
using paper?

Assuming the former, lets look at your suggesting for plotting position using
grid squares:

... de WB4APR @FM18SX...

Looks good, but without understanding how varicode works its far to verbose.
Seems strange to say this, but with PSK31 we don't have the luxury of 1200
baud.... the data stream is only 31bps. Maybe a link to the theory of varicode
would
be helpful:

[http://www.kender.es/~edu/psk31theory.html#Information Coding](http://www.kender.es/~edu/psk31theory.html#Information%20Coding)

OK, so lets look at how long your example is:

de WB4APR @FM18SX which is 17 chars including the de, space and delimiter.

Now, transcribing this to varicode we get the following (bit length under char)

d	e	_	W	B	4	A	P	R	_	@	F	M	1	8	S	X
6	2	1	9	8	8	7	8	8	1	10	8	8	8	9	7	9

for a total of 117 bits + (16*2 sync bits) = 149 bits @31bps = 4.8 seconds
to send a very ambiguous posit that is not very computer friendly.

another way to do it would be as follows and could be part of the PSK31
ID string delimited as follows:

<call in lower case><aprs delimiter><lat><lon><optional checksum>
example for lat 39.0858, lon 763601 (note "_" is space):

wb4apr-ts_rarln_tn_e (see conversion table below)

Now, transcribing this to varicode we get the following (bit length under char)

w	b	4	a	p	r	-	t	s	_	r	a	r	l	n	t	n	_	e
7	7	8	4	5	5	6	3	5	1	5	4	5	5	4	3	4	1	2

for a total of 84 bits plus (18*2 sync bits) = 122 bits @31bps = 3.9 seconds.
A ~19% savings in air time giving a precise posit that is very computer
friendly. This could be a standard ID frame that is sent with each station.

here is the conversion table:

Char	bit pattern	Could be?
SPACE	1	0
e	11	1
o	111	2
t	101	3
i	1101	4

a	1011	5
n	1111	6
l	11011	7
r	10101	8
s	10111	9

Now, taking this a step further, we could go with base100 for our lat/lon and save those two bits for sync on the lat lon chars (as we are going from 12 chars to 6). We offset with 32 then take the four smallest varicodes from under 32 as 0-3 (all varicodes under 32 are 10 bit) and this gives us a average varicode length of about 8.

So we could have something like this for lat 39.0858, lon 76.3601

wb4apr-C\$Vh@<LF>

Now, transcribing this to varicode we get the following (bit length under char)

w	b	4	a	p	r	-	C	\$	V	h	@	<LF>
7	7	8	4	5	5	6	8	9	9	6	10	5

for a total of 89 bits plus (12*2 sync bits) = 113 bits @31bps = 3.6 seconds which is a 25% savings in air time.

Now, I haven't consider the ones place or sign for either lon or lat, but this could be delt with in the delimiter field.

The advantages are:

1. A easily machine parsable format
2. Far more precise location then "grid squares"
3. A significant savings in air time.

Give it some thought.

-Jeff

Jeff,

I am approaching a merging of APRS display technology from the perspective of the existing PSK31 user base. Look at any PSK31 QSO. They already use GRID SQUARES. SO parsing and displaying that in APRS is a natural, and can be done NOW and requires NO CHANGE IN existing operator technique. You do it on receipt... Thus you can begin plotting people NOW.

Your unique selection of varicode characters can save 19% over a "grid square" but I bet you will never convince anyone to use it. And it must be implemented by all SENDERS before it has any value. Good luck...

You are trying to optimize around "computer friendly". I am trying to optimize around "user friendly" and taking advantage of existing use...

I understand how varicode works. I also understand how operators work and how they are already using gridsquares and they could care less about changing just so us APRS people can plot them...

> Now, transcribing this to varicode... 117 bits ... or.. 4.8 seconds to
> send a very ambiguous posit that is not very computer friendly.

Not ambiguous at all when you consider that PSK31 is being used on HF,
Internationally. The Grid plots the guy to within less than 2 miles in
most areas of the world and is well close enough for an HF DX contact in
my thinking...

> [ALTERNATELY consider:] wb4apr-ts_rarln_tn_e
>
> Now, transcribing this to varicode we get 84 bits for 3.9 seconds.
> A ~19% savings in air time...

Savings? You saved 0.9 seconds in a 1 minute long transmission...

> giving a precise posit that is very computer friendly.

PSK31 does not need to be computer friendly at all. With its VERY
precious bandwidth, it needs to be MAXIMALLY *user friendly*. With the
computer power we have today, we should make the computers work for US,
not make us REDEFINE HAM radio QSOs so the "computer" is happy...

> Now, taking this a step further...: wb4apr-C\$Vh@<LF>
> ...ranscribing this to varicode we get a 25% savings in air time.

No, you get another 0.3 seconds saved in a 1 minute QSO... Savings?

> The advantages are:
> 1. A easily machine parsable format
> 2. Far more precise location then "grid squares"
> 3. A significant savings in air time.

Ah, BUT... DISADVANTAGES:

1. No one will use it.

> Give it some thought...

I already did a year ago and suggested something like it to Peter Martinez
back then, but we both concluded it wouldnt fly. Grids are already in
use. We use them in APRS too, so it just seemed like the logical way to
go...

It is very easy to write a parser that can recognize a GRID SQUARE just
about anywhere in free form TEXT. APRSdos, WinAPRS and APRS+SA and maybe
others already have such algorithms..

bob

Jeff, Bob, et al...

I tend to agree with Bob on this one. I say that fully understanding the ramifications of even uppercase characters in varicode. This is not intended to be a system to replace what goes on HF packet. My idea was so that when someone is out in the field, they can send a message or a posit back via

PSK31 because with a mobile rig and a computer, I think I can get into the network better on PSK31. If we talk about 1 watt, a battery, and a dipole, the odds of success over HF packet go even higher. Perhaps, my approach of a PSK31-based mail exchange system is different than just a posit-type system. Remember that my idea was to put a macro in an existing program like Digipan. If we make the data computer-friendly, then no one will be able to put it in Digipan.

Which is fine. But I was approaching it from the perspective of the APRS user base..... tracking assets. I have little interest in HF chit chatting but if one can bootstrap off existing technology to enhance amateur AVL, which is my interest, then I think we should.

- > Look at any PSK31 QSO. They already use

- > You do it on receipt... THus you can begin plotting people NOW.

Why can't we do both then? I'm interested in tracking assets, not peoples houses. As such, I need to target platforms that will support this. A laptop in a vehicle is not practical in all applications. However, a PIC processor is. And there already is open source PSK31 code out for the PIC. Sure, I could send grid squares with the PIC, but gezz, how big would the look-up table be? I'd have to relate lat/long to every grid square. Why not just make life easier for everyone and just send lat/lon as that's what the GPS gives me?

- > Your unique selection of varicode characters can save 19% over a "grid
- > square" but I bet you will never convince anyone to use it. And it must

Actually, I was trying to convince you to look at the big picture here since we have a relatively clean slate. I'm not saying not to use grid squares, I was suggesting a alternate method that allowed the use of a GPS to track assets using a minimal processor. As a side benefit, it could be more compact then grid squares, easier to parse and more precise.

Bob, I don't understand your resistance here.... you have what, four or five different ways to say the same thing on AX.25 aprs?!? I was throwing some ideas out here and thought I could get some dialog on the issue... so far I've gotten one guy arguing the merits of RTTY over PSK31 and now you shooting the idea down before it even gets out the gate. I think what I had was a very good way to use PSK31 to track assets..... yes I should code something up, but that shouldn't curtail intelligent conversation on the subject.

- > You are trying to optimize around "computer friendly". I am trying to
- > optimize around "user friendly" and taking advantage of existing use...

Yes, guilty on all counts.. I don't care at all about existing use.... I'll use the internet to chat with someone sitting at their house. What I was interested in was bootstrapping a existing technology into tracking mobile assets. Seemed like a good fit to me.

- > > Looks good, but without understanding how varicode works its far to verbose.

>

The application of PSK31 Thomas suggested and I expanded upon does not yet exist. So the existing "user base" is irrelevant. Its just a modulation method Bob,
that's all. I could (almost) care less about the existing user base as any tracking operations would not be on the same frequency as the existing user base.

> > Now, transcribing this to varicode... 117 bits ... or.. 4.8 seconds to

If there is no APRS coverage in a particular area, AND I can send locations to within 10's of feet, why not do it? I'm not going to jump on the emergency bandwagon, but in some terrain's a grid square would be close to useless in locating someone.

Again, I think the basic misunderstanding here is you are interested in tracking houses (which don't move) and I am interested in tracking assets (which do). Why close your mind at the beginning of the game? I'm not saying what I suggested was the way to go, but just because you don't see things that way doesn't mean they can't be used that way. Don't tell me about how the users won't accept it... tell me why it won't work or why you will not support it within the context of your role in APRS.

> With its VERY
> precious bandwidth, it needs to be MAXIMALLY *user friendly*. With the

PSK31 is a mode. It has nothing to do with a QSO. Yes, it was optimized for QSO's and frankly, posits would be better served by tossing varicode, yet I am aware of the value of bootstrapping.

> > Now, taking this a step further.... wb4apr-C\$Vh@<LF>
> > ...ranscribing this to varicode we get a 25% savings in air time.
>
> No, you get another 0.3 seconds saved in a 1 minute QSO... Savings?

The example I gave where ID/posit frames. Self supporting. Nothing to do

with QSO's. Savings as posted.

Again, you are putting your views in what APRS should be into this discussion, which is coloring your thinking. It appears to me your goal is to "sell" APRS to the existing PSK31 user base. This is fine, but it is a separate discussion. If you go back to the original posting that started this thread, you'll see the poster clearly wanted to graft PSK31 to APRS, not graft APRS to the PSK31 user base. As such, my comments about air time savings are entirely relevant and correct. (although it appears now he strangely agrees with you.... not matter, doesn't change my thoughts)

> Ah, BUT... DISADVANTAGES:
>
> 1. No one will use it.

Yes, indeed, especially with the overwhelming support I am seeing from you.

> It is very easy to write a parser that can recognize a GRID SQUARE just
> about anywhere in free form TEXT. APRSdos, WinAPRS and APRS+SA and maybe
> others already have such algorithms..

OK, then lets get back on focus in your line of thought. I am willing to roll over and play dead if you help me here.

I've been looking at PSK31 for use in trackers. Even posted some mind storms on it back in January on the PICSIG. A fellow has written some PIC source with CCS C compiler to do PSK31 and it is freely available. Its actually everything all rolled into one. I've gone through the source, and it looks like I can do what I want.

Yet you say its very easy to write these parsers for grid squares, or in the case of a tracker, the lookup table to convert a precise lat/lon to a fairly imprecise grid square. Yet you are laboring under the false assumption that a PIC is a full blown PC. Its not. It only has up to 368 bytes of RAM and often less then 4K of memory. As such, the direct path is often the best path to take. In this case, directly sending lat/lon instead of having a large lookup table with grid squares. Yes, pick and chose your varicode, but still way smaller then a massive lookup tree.

So... suggest a method to do these grid square lookups then in these

constraints... maybe you
know something I don't about putting 300lbs of groceries in a 5lb bag.

And if anyone is interested in this project, I can try to help. I'm busy now
myself with
another AVL project, but I'd like to help anyone I can here. I've talked with the
author of the PIC PSK31 transmitter, and he was very supportive of anyone grafting
APRS support onto it. See http://www.ussc.com/~turner/psk_transmitter.html
It is written in CCS PCM, and I can help anyone with this if need be (I've written
alot of PIC code myself on CCS, and even a few little things for the TAPR
project).

So however we do it.... grid squares or real lat/lons, we are alot closer to a PIC
based PSK31 tracker then we think. Most of the work is already done. Lets not
throw the baby out with the bath water in our passion. Worst case, we can just
start with a inefficient, but existing APRS protocol and work down from there, but
IMHO, grid squares/lookup tables are not practical in most mobile trackers.

Regards,

Jeff

If we take the PIC example, then I agree we need to maximize everything. That discussion is the same as MIC-E. It is a smaller compressed protocol that humans cannot understand, but the computers do. The only issue there is that I need a program that rapidly scans some area on a band (like 14.070) and gets data. The PIC would then just beacon. The problem of course is that I may not be listening in a certain area when you decide to beacon. Beaconsing twice could help this problem.

If you look at the speed of the algorithms, it should be quite fast to jump to the next signal on the band, see if it has any POSIT qualities, the jump to the next one. Perhaps, if the POSIT was aprs aprs aprs aprs de ny4i|<posit info>|. The receiver would have a better chance to find the preamble and stop.

If we want, this can be taken off to the arpp list one onelist.

Tom

Ian's final draft has been in the hands of the group for a while now, and we're scheduling to close the review and have a final vote by the end of July. With luck, the final release will follow very shortly after that (Ian will just need to make whatever final tweaks there are and change the title to final form).

73,

John N8UR

I agree, that it would be ideal to use PSK31 techniques for much better HF success. But it cannot operate as a dumb tracker, since the tuning has to be within a fraction of a HZ. Thus the sender either has to match an IGATE beacon or the IGate must auto-tune the tracker. Both of these take time... and I doubt are practical.

Thus, you are back to square one, needing operators at both ends, and thus back to a human QSO, etc.

If you can make it automatic, then I am all for it!

Bob

I'm trying to remember WAAAAYYY back to the beginning of this thread, but I believe the whole thing started with a "suppose" like: "Suppose you had a program that decoded all the PSK31 conversations in the passband of your receiver...." It would look at the entire 2.5 - 3.0 kHz swath of incoming stuff, like the frequency waterfall in DigiPan, but decode ALL the incoming data streams, monitor them for stuff like "DE W8ABZ@EN91fm" and plot them on your map.

I don't know DSP, so I don't know if it's possible (with a sound card at 44 kHz sampling with a big honkin' Pentium Ninety-Twelve at 10.5 GHz) to decode ALL the PSK31 data in a 3 kHz passband, but I think that would be a cool program. Might also program it with user-enterable rules, like to look for rare DX calls, stations not yet contacted on the current band for a contest, the word "emergency" or "mayday", or whatever else. (Bet the FCC could use it, too, if they're not already... ;-) Anyway, the point of this is that the original premise was that you wouldn't need exact tuning because you'd be decoding everything in the passband.

At least, I think that was the deal. Could be wrong. I'm the same idiot who thought I should use the output of the sound card with a stereo gen chip to FM the clock on a 100 MHz Pentium so you could broadcast to any Walkman or other stereo receiver in your house. Silly me.

Regards,

Dale

I have just produced a new test suite for Mic-E software. It consists of
around 200 carefully crafted packets, designed to stretch the Mic-E
software in all directions.

I am not posting it to my website just yet, but if you would like a copy
(about 30KB) just drop me a mail: g3nrw@tapir.org

Here's the output of APRServe's parser if anyone cares to write a program
to reconcile Ian's report format with the converted packets, or perhaps
Ian would like to run this through his program and diff the result...

Too painful to go through a couple hundred lines by hand...

>

Steve, I've just endured the pain. And I'm sorry to say it **was** painful. There are **many** errors in your conversions.

I'm attaching my comments (in 3 parts to allow me to post here).

In summary, there are 5 common errors:

1. Latitude conversion of packets containing Custom message codes is completely wrong.
2. Custom message codes are incorrectly interpreted.
3. Position ambiguity is, er, ambiguous. Well and truly screwed, with some wrong hemispheres (e.g. West instead of East), and in one case 20 deg long became 120 deg long.
4. Reports containing symbols with numeric overlays were not converted for some reason.
5. The raw data had several sections containing bad packet data. None of these packets should have been converted.

Here is part 1 of my comments. Errors are underlined with ~

PART 1 of 3

That was a "real" bug, a precedence problem...easily fixed with a pair of
parentheses. Thanks.

>5. The raw data had several sections containing bad packet data. None of
>these packets should
>have been converted.

>

I don't agree...garbage in, garbage out. My code is supposed to be a

conversion, not a validation. If the packet is simply dropped, there is no clue as to why there is a problem. But if someone is writing a Pic-E program and makes a mistake, it is far more helpful to them if they see that the converted latitude is 150 degrees than if the packet simply disappears.

Am I correct that the validation suite did not catch the 0.01 problem that precipitated all this? Or did I just miss it in the printout? Which of the test cases, if any, were supposed to (or did) pick this up?

I don't know when your code was "completed", but custom messages and position ambiguity were documented *years* ago by Crosswell and Parsons (I don't have the document to hand right now, but it appeared long before the current spec).

Problem is, your garbage out wasn't generated consistently, so in most cases it bore little relationship to the garbage in. This is totally useless in diagnosing faulty PIC programs -- and if *good* data in produces *garbage* out, what chance does anyone have?

In any case, the world-wide APRS Internet is not the place to be testing such programs.

>Am I correct that the validation suite did not catch the 0.01 problem

The "longitude hundredths" sections were intended to do this.

The bottom line is that APRServe is badly broken. As a result, many people throughout the world have spent many, many hours trying to track down the source of bad packets (totally wrong Custom latitudes, wrong custom message codes, latitudes with 3 or 4 digits after the decimal point, latitudes > 90, wrong hemisphere, longitude off by +/- 100 degrees, no position ambiguity, etc, etc).

You said the other day that Dale did a great job in fixing aprsd. Now, *perleese*, do the same with APRServe.

And ditto to anyone else who is using APRServe-related code. With bugs propagating around the world in minutes, this sloppy, amateurish, arrogant attitude to programming has to stop.

Well, attached is the mic_e.c file from Alan circa 5/97, it has no
mention of either, my code is of the same vintage. To the best of my
knowledge, both of these features originated in the D-700 within the last
year or so. These just suddenly appeared in a finished product without
prior notice (at least to me), an example of why the APRS-WG was needed.

Want more proof? Look at

<http://www.aprs.net/vm/DOS/MICE.HTM>

This was the Mic-E documentation file of APRSdos in 8/97. It also has no mention of either.

Who are these "many people" that spent these "many, many hours"???

This code is only applied to input from the TNC...unlike aprsd, APRServe only converts local Mic-E packets. Therefore, it appears you are making up "throughout the world". At its peak APRServe ran in 4 locations, it is presently running in 2. So unless you care to argue LA and Milwaukee (and previously including Nashville and Miami) are "throughout the world", you are displaying your own bias towards making the problem seem far more important than it is.

>You said the other day that Dale did a great job in fixing aprsd. Now,
>*perleese*, do the same with APRServe.

>

I never said I wasn't. The fact that I exposed my results publicly, to what I was sure would be your demeaning attitude (and you didn't disappoint) shows my willingness to improve in this area.

I'll be dropping Dale's procedure into APRServe when I get a chance. He passes it a broken up packet and output buffers, I pass in the full packet. If someone wants to convert Dale's procedure to the later format it will happen sooner, undoubtably to the great relief of the many temporally-challenged people in SoCal and Milwaukee...

>And ditto to anyone else who is using APRServe-related code. With bugs
>propagating around the world in minutes, this sloppy, amateurish,
>arrogant attitude to programming has to stop.

>

You make statements like this, then when I call you on them you say you weren't insulting me. This sure seems like a direct insult. There is nothing sloppy or amateurish about this. A new feature is added after active maintenance of a program has ceased. No one ever complained about the lack of support for these two rarely used features. I was working on other things. It never got done, just like the 30 other things on the APRServe do list, and the hundred or more on the javAPRS list.

Like Dale, I feel an obligation to try to keep my old program useful, but frankly with just two sites it isn't that high a priority to me. That I've moved on to findU, something I find far more interesting, and that affects far more people, doesn't make me sloppy or amateurish. And as to arrogant, I'd say this message shows you are as deserving of that label as I.

Ian did a great job with Mic-E Test Set. Though I am not implementing
internet gateway service or Mic-E tranlating digipeating, it will be used
for general program decoding validation.

Now, PLEASE, lets have a similar set of basic APRS packets!

Hi to all...

I've been thinking about the problem of the network architecture et the whole duplicate packets that been going on last week. I concur that the problem is real and many connection are probobly made and that could be without.

The idea of central servers should still be there. How many? Good question. I'd say at least 3 which could be fully redundant between them.

The problem of the growing number of IGATES and the idea of managing them all is totally a bad idea. I most give that to Steve. But if the idea of satellite-regional servers be implemented, or a derivative, it may solve the problem....

The idea is quite simple. With small machines (i.e. 486 with low memory), could get data for a certain region and be responsible for that small region (messages, posits and all that good stuff). Those small machine would send to regional servers responsible for few smaller machines.

For access, the smaller machine would not warrent high bandwith, and would just require to be connected to the internet and reach a bigger server. Then the regional servers could connect to the main servers and then these server could be managed. Each responsible of the regional servers would be responsible for their server and region...

Yes this puts more responsibility on more person, but it could be managed more easily. Pin point to a person to rule out the problem, either on his own IGATE to block the traffic from a station or any other way he will suite fit. This could limit the propagation of the feeds....

Yes this involves work but I guess we need to put a bit of control in our network. Not too much so that it becomes a pain but just enough to still make ths way of communication fun.

The next release of aprsd will have a couple of minor bug fixes and while I'm tinkering with the code I may as well modify the Mic-E converter so it doesn't have the time stamp. Bob suggested making the first information field character a "=" for Kenwoods because they are message capable and "!" for others. I also propose changing the "E>dsy" field to "Mic-E".

The Mic-E comment field will be passed unchanged.

Examples.

A packet which now converts to:

```
WU2Z-9>APD213,WIDE,WIDE:@092142z4031.28N/07427.74Wv297/000/E>dsy/M0/Off  
duty.. ]"5g}
```

Will look like:

```
WU2Z-9>APD213,WIDE,WIDE:=4031.28N/07427.74Wv297/000/Mic-E/M0/Off duty.. ]"5g}
```

A non-Kenwood packet such as this:

```
KD5AMB>APD213,OKCITY*,WIDE:@092142z3532.83N/09736.94W>000/000/E>dsy/M0/Off duty..  
PIC-E Moble testing mark@grennan.com
```

Becomes:

```
KD5AMB>APD213,OKCITY*,WIDE:!3532.83N/09736.94W>000/000/Mic-E/M0/Off duty.. PIC-E  
Moble testing mark@grennan.com
```

YES! I've had to strip off the timestamps in my dupe-check code
because each MIC-E expander adds it's own local timestamp. Excellent
idea just getting rid of it.

I love the other changes too, except why have the "/Mic-E" part at
all? It's evident to me that it's a MIC-E packet because of the "/M?"
part of the packet.

My personal preference would still be to not have the MIC-E packet
changed in any way by the igates or findu or whatever, but just have
it decoded in the client programs. Since that is probably not
forthcoming, the above changes will certainly improve things a lot.

What programs do not handle Mic-E?

- 1) APRServe
- 2) others?? FindU??

APRSD handles Mic-E fine. All other client program that I know of handle Mic-E find. If we convert Mic-E to "=" or "!", we break the APRS protocol where by "=" and "!" indicate fixed stations. This is a bad idea...

I propose we eliminate ALL conversions of Mic-E. Changing APRSD does not change winAPRS or macAPRS or APRS+SA or APRServe. Changing only APRSD will only continue to propagate the duplicates. APRSD should never convert a packet it has not heard via RF directly. APRSD handles Mic-E fine. We need to address the programs that do not handle Mic-E, and that is only APRServe, correct? Fix that and the problem goes away. Perhaps, APRSD should be THE program for the Internet system, eliminating all APRServe sites. How many are there? Would a 486 be sufficient to run Linux for APRSD?

More comments?

APRServe handles Mic-E fine, though as Ian pointed out there are some things that could be improved with the conversion. If and when a standard is agreed to, and is implemented in aprsd I'll port Dale's procedure over, but this only affects things heard on RF, in the Socal and Milwaukee areas.

Perhaps you have not noticed the dozen or more times I've addressed this issue, but APRServe is transparent to the non-printing characters used in the Mic-E. When the problem first surfaced, I took the blame for it, which turned out to be a mistake. The problem is in the clients (including my Mac-based test program...the cause of my misperception of guilt), not in APRServe, however despite the many times I've said this on the SIG, the perception still seems to be that APRServe is dropping the chars. However, when it is tested from a Linux client, the characters pass through fine.

Please, I've said this over and over, since I have found out it really isn't my fault. Can we put this urban myth to rest? Please???

>2) others?? FindU??

>

True, because it hears the data directly from aprsd, which converts all Mic-E packets, I didn't write code that would never be used.

I guess I have been asleep, I was still believing what you had said about APRServe in the past. No, I have not noticed dozens of times you said APRServe was not at fault. If APRServe and APRSD handle Mic-E correctly, then FIX the client programs that do not decode it correctly. Lets eliminate conversion of Mic-E everywhere. Converting them to "=" or "!" violates the APRS protocol.

Yes, lets change APRSD's method of converting Mic-E packets - eliminate the conversion.

It is not a decoding problem, but a communication problem. The
non-printing chars are lost before they get to APRServe.

The point is, it is a Client problem, not APRServe/APRSD. Fix the clients.
Eliminate the conversion of Mic-E.

Ok, eliminate the conversions, AND fix the communications problems. If an application strips the non-printing characters after the conversions are eliminated, those applications won't be a problem for long.

Lets do as Brent suggests and stick with the spec. Creating ad-hoc fixes to the protocol is a recipe for disaster. That is how we ending up with the Mic-E duplicate mess to begin with. We still do not have a WRITTEN spec for conversions anyhow.

Bill KC9XG

On Thu, 10 Aug 2000, Curt Mills, WE7U wrote about Mic-E conversions

> I love the other changes too, except why have the "/Mic-E" part?

That field is my preference, because in APRSdos, I use that field to display the following four types of packets differently...

WU2Z-9>APD213,WIDE,WIDE:!4031.28N/07427.74Wv297/000/Mic-E/M0/Off duty..
WU2Z-9>APD213,WIDE,WIDE:=4031.28N/07427.74Wv297/000/TH-D7/M0/Off duty..
WU2Z-9>APD213,WIDE,WIDE:=4031.28N/07427.74Wv297/000/D-700/M0/Off duty..

I would prefer that Dale's conversion also do these insertions so that we can see what kind of station the guy is. It makes a difference as to whether you can send him a message or not...

> where by "=" and "!" indicate fixed stations. This is a bad idea...

No, there should be no such association. "=" and "!" formats have always been for Position Reports *without* a time stamp. Although this has been usually applied to non-moving fixed stations, this is not the definition of the format. Yes, we even called it "fixed" stations, but that was a label of convenience, not a label of function...

These two formats were introduced in the 1996 time frame to avoid the problems with unsynchronized PC clock's for positions in which the exact time is not important. The Mic-E originates without a time stamp, so this is why we think conversion to the "=" and "!" timeless formats (if needed) is the way to go.

I'd sure like to do that if the side effects aren't too severe.

Regardless of whether the packets are conveted or not, the timestamps
on Mic-E will be gone. What about the aprsd history dump? Users logging
onto port 10151 will get n minutes of history including these old non-time stamped
packets. Any potential problems there?

Allan has raised an issue by implying that the NWS WARNING messages used as an EXAMPLE in the SPEC are an affront to the INTERNATIONAL flavor of APRS. In looking at the spec, the causal reader might infer that it is another APRS FORMAT that is unique to the USA.

THIS IS NOT THE CASE. The NWS format is not a special format and is just an example of the use of the STANDARD APRS MESSAGE for a special application. But this is not obvious to the uninformed reader.

Therefore to avoid such continuing criticism of the spec, I would suggest that the NWS WARNING PARAGRAPH be re-worded as follows:

NATIONAL WEATHER SERVICE BULLETINS:

Standard APRS message formats can be used for a variety of other applications. For example, in the USA, special formatted messages addressed to the generic callsign of NWS-XXXX are used to color highlight map areas involved in weather warnings using the following format....

This clarifies that this is NOT another unique format, but is simply another message. By including it as an example, we are showing how the APRS MESSAGE protocol is NON-RESTRICTIVE and has INFINITE EXPANSION capabilities for other applications.

Yes please! This is the RIGHT way to do things. The others are
just patches. 8-bit transparent networking code is not particularly
hard to write these days.

Let's also fix the client programs so that they set:

```
afilter off  
mfilter 0
```

for AEA TNC's while we're at it, so we can get those non-printable
characters passed through those TNC's. That'll fix a few of the
clients that are running older TNC's (like me!).

That should be easily fixed too with a bit of code (isn't it always "just a bit more code"?):

For your history queue, add a time stamp in some format that is unique to you and easy for the C++ code to recognize/strip off again. It can be stripped off as the packet is being sent to a client, but used internally to aprsd to expire the data out of the queue.

I don't implement the 30-second history, but here's how I'm doing the 30-second dupe-check queue: I use a reduced form of the packet itself as the hash key (removed digi's, removed timestamps, removed white space). I store seconds-since-Unix-epoch as the value of the hash entry. With this method I save the time that -I- received the packet as the timestamp (ignoring the timestamp in the packet itself), and keep it as a separate variable from the packet data. So far this has worked well. It doesn't matter whether the packet has a timestamp or not as I'm generating and keeping my own timestamps internally. An added feature of this is the varying timestamps in MIC-E expansions don't affect my dupe-checking. I can treat the hash as a circular queue to expire old data, or treat it as a hash to find out if I just received a duplicate. In my code I do both.

Let's keep this idea of fixing the clients going, and if we don't have to base-64 encode the stuff either, everybody wins all the way around.

And pressure would be exerted on the authors to update their programs.
Could be a bad thing overall, could be a good thing. It would hurt
temporarily until it was healed though.

> Who wants to volunteer to test all the client programs?

Perhaps the authors of the individual programs and their individual
groups of beta-testers?

I'll help test and fix Xastir if it needs it. I think that's the
only client source code I have access to and care to run.

I think you misread Dale's question. He does not use it, he uses his own
time field. The question was how would this affect the clients? My guess
is not at all, the timestamps on APRS packets are worthless because of
all the troubles with people incorrectly setting their clocks.

findu totally ignores them, using only the time received.

Before this happens a few things ought to occur. First, someone needs to
test all the client programs to determine which ones need to be updated.
Then those programs must be updated, and those new versions widely
distributed.

To eliminate the conversions before this is done would result is a large
number of erroneous positions on the internet feed, a situation far worse
than that we have today.

Who wants to volunteer to test all the client programs?

Steve K4HG

Are you sure? Here's what Dale wrote again:

> Regardless of whether the packets are conveted or not, the timestamps
> on Mic-E will be gone. What about the aprsd history dump? Users logging
> onto port 10151 will get n minutes of history including these old non-time
> stamped

He specifically mentioned port 10151, which has a 30-second history
queue normally. Port 10152 does not, it's live data only.

Since he wouldn't be expanding the MIC-E to have a timestamp, it sounds from the above that he would have old MIC-E packets hanging around in his history queue forever (not getting expired out). They would be downloaded to the client program when they connect.

That's why I went into the speil about how my dupe-check queue worked.

Did I understand you correctly Dale? If not, I need to get more of this diet pepsi into the bloodstream this morning.

Steve is correct. All the history packets are timestamped with both unix time and a (now redundant) time to live value. Also, the latest version of aprsd uses a completely separate method to do dup checking. I was indeed concerned about user programs getting old, untimestamped Mic-E data from the history buffer when they log on. Some aprsd operators set the history expire time to as much as 8 hours.

So where's the problem? If you're time-stamping everything in the history with unix time, everthing gets expired from the history queue properly in any case. Aprsd is already written correctly and would require no tweaks other than getting rid of the MIC-E expansion.

If users are connecting up to an internet server on a port that provides history, they should know by now that the client program aging of packets might not be correct. Xastir already works that way I think. It ages the icons based on when it received them, not based on their timestamps. Perhaps the other client programs actually check the timestamp? If so, then I see where my confusion comes from.

Hopefully there are no problems or side effects.

This is almost never the case in the real world however.

I asked the question to see if anyone could come up with potential
pitfalls.

Here's another question: When an unconverted Mic-E pkt is gated from internet to
RF as

a 3rd party reformatted packet, will the client software properly extract the
posit data from the ax25 destination field ?

APRSdos will. The 3rd party format is totally recursive in APRSdos
bob

To convert or not convert, that is the question.

It turned out to be trivial to put in a new keyword in aprsd.conf.
ConvertMicE yes | no
The actual code to select convert or not was also trivial.

Now the I need to decide if the default should be "yes" or "no"
if "ConvertMicE" does not appear in the config file.

The 3rd party reformatting also seems to work.

Original packets:

```
WA4DSY>0000P0:`vX      >/      (0x1c)
WA4DSY>675900:`012345>/
WA4DSY>PPQRST:`012345>/
```

ConvertMicE no

Sending to TNC: {WA4DSY>0000P0,TCPIP*,WA4DSY-1*:`vX >/ (0x1c)
Sending to TNC: {WA4DSY>675900,TCPIP*,WA4DSY-1*:`012345>/
Sending to TNC: {WA4DSY>PPQRST,TCPIP*,WA4DSY-1*:`012345>/

ConvertMicE yes

Sending to TNC: {WA4DSY>APD214,TCPIP*,WA4DSY-1*:!0000.00S/00000.00E>004/040/Mic-E/
M7/EMERGENCY. (0x1c)
Sending to TNC: {WA4DSY>APD214,TCPIP*,WA4DSY-1*:!6759.00S/02021.22E>025/232/Mic-E/
M7/EMERGENCY.
Sending to TNC: {WA4DSY>APD214,TCPIP*,WA4DSY-1*:!0012.34N/12021.22W>025/232/Mic-E/
M0/Off duty..

Looking at the last APRS spec that I downloaded, the example for a compressed object is not correct per the text. The example has no time field, but the text says it is required. Hopefully someone else has caught this before now.

The compressed format only covers the LAT/LONG and CST fields 'wherever'
they occur. Thus they can be with or without time fields.

Don't discount this so quickly Bob! Read the spec for "Objects" using the compressed lat/lon. The "Object" text specifies that a timestamp is REQUIRED. The example in the table shows an object WITHOUT a timestamp. Either the text or the example is incorrect. Not a big deal, but it IS incorrect.

Thanks! Yes, the OBJECT format does require a time stamp. So I agree,
th eexample is bad...

A new version of aprsd is available at:
<http://www.wa4dsy.net/Files/aprsd214.tar.gz>

The doc file can be viewed at:
<http://www.wa4dsy.net/aprs/aprsdDOC.html>

The most notable change is the server defaults to NOT converting
Mic-E packets to classic APRS format. The Sysop can elect to convert
if he needs to.

Here is a list of the changes:

REVISIONS

2.1.4

- 1) Fixed DeleteSession() so it can't delete if port number is -1
and made ConnectedClients a signed integer. Hopefully this will
prevent errors in the user count.
- 2) The dup detector now ignores trailing spaces
- 3) Put Location info on the html status page
- 4) Deal with mic-e timestamps as per this email from Bob on Aug 3 2000.

"We should not have included the timestamp when the conversion was done by an IGate just for the reasons that we dropped the time stamp in all other stations back in 1996.

It was a mistake and we should fix it by simply replacing the "@DDHHMMz" portion of the conversion with a "!" for TAPR Mic-E's and to a "=" format for Message capable Mic-E's (Kenwoods). This would eliminate this nuisance immediately. "

5) Fixed bug in HUB connection logic that caused it to advance by two instead of one

after attempting to connect to a hub that was down. If only 2 hubs were defined

it would always retry the same dead hub over and over.

6) Added command "LogAllRF" to aprsd.conf. When set to "yes" all packets heard from the TNC

will be written to /aprsd2/rf.log instead of only packets with our call sign as was the case.

7) Added keyword "ConvertMicE yes | no" to aprsd.conf file. If this is set to "yes"

Mic-E packets will be converted to classic APRS packets, otherwise they will pass

through unchanged. Default is "no" .

8) Cleaned up some code in history.cpp: createHistoryArray(aprsString* hp) so it now

aborts a history dump if memory allocation fails. The original code ignored a malloc failure.

I applaud the step in making Mic-E conversion optional; I feel it should be eliminated. I think it is wrong to change the conversion of Mic-E to type "=". It has long been stated that type "=" is a fixed station type, and I strongly feel it should be still considered a fixed station type with computer. Mobile computers are of type "@" and the timestamp is acquired from a GPS receiver and thus provides very good accuracy for the timestamp. Fixed computers do not move, do not need to have a GPS receiver and should have a way to indicate this. Calling "=" type packets not fixed is protocol revisionism, and is now being applied Mic-E converted packets. It has been clearly stated in the past the "=" was for fixed stations. By having APRSD convert Mic-E to "=" will only compound the conversion problems because this does not change the way APRS+SA or WinAPRS or other client program converts the packets. Fortunately, the default is to not convert them.

Final side note, APRSD appears to be 8-bit data compatible, APRServe is 7-bit. Both do appear however to handle Mic-E data OK.

APRS format *type* characters (!/=) do *not* specify types of stations,
they specify ONLY the *format* of the packet. The "=" *type* simply means
a format without a TIME STAMP. It has nothing to do with the type of
station and it never did.

> Mobile computers are of type "@" and the timestamp is acquired from a
> GPS receiver and thus provides very good accuracy for the timestamp.

Sorry, you got it backwards. Mobiles use the "@" format because they are
going to include the time stamp, not because they are mobiles.

I am sorry, but nothing has been revised, only you are now finding out
that your "interpretation" must have been wrong all along. The "=" format
was always defined to be a *format identifier* for a position report

without a time stamp. It had nothing to do with the type of station. I am sorry if you missinterpreted it.

This "=" format happened to be very appropriate and was used for FIXED stations where the time stamp was usually useless... but the *type* of packet never "defined" a *type* of station. Yes, we all agreed that it made sense for FIXED stations to use this format, but not the reverse.

Bob

APRServe will continue to do it, and www.aprs.net will have the aprsd option turned on. Regardless of what may be "pure", the reality is there are clients that are not able to handle the data. I feel that backwards compatability is important, and until all versions of the program have

been verified to be able to send and receive the Mic-E data, I will continue to do the conversion at the network level.

This would be a nice task for an individual to take on, to test each version against the Mic-E data...

My recollection is the same as Bob's on this point. I do not recall the difference ever being defined as fixed vs. mobile, only timestamp vs no timestamp.

>Final side note, APRSD appears to be 8-bit data compatible, APRServe is
>7-bit. Both do appear however to handle Mic-E data OK.

Nice to have independent confirmation, perhaps this will put the persistant rumors that it is APRServe's fault to rest...

The 7 bit limitation is deliberate on my part, as APRServe is designed to handle TNC text only, the 8th bit is masked off on each character. It could be removed easily if there ever were a reason to pass 8 bit data.

We have called if fixed, you have called if fixed. It is appropriate to call it fixed because the implications of using "=" without a timestamp was because it was for stations that would not change their Lat/Long frequently. Now the only way to differentiate a fixed vs mobile station is to observe that there are more the Lat/Long for the station. So be it. But I think it is wrong.

I will quote Bob from just a week ago:

"No, there should be no such association. "=" and "!" formats have always been for Position Reports *without* a time stamp. Although this has been usually applied to non-moving fixed stations, this is not the definition of the format. Yes, we even called it "fixed" stations, but that was a label of convenience, not a label of function..."

Yes, we have called it Fixed stations. "=" Fixed stations with computers, "!" Fixed stations without computers. We have used this terminology in discussions for a long time.

But @ has been used all along for weather reports from fixed stations. My
recollection remains that these were not limited to either mobile or
fixed use, only as to whether the data was time related.

Yes, that is true. I have felt we should have a unique identifier for WX packets, but we have not agreed on that with using both "@" and "_" type packets for weather where the latter provides no additional information over the prior. I still strongly feel that the timeless packet types should be reserved for fixed stations, it adds useful information that can allow quick determination of a stations type. Moving stations have (should) ready access to a very accurate time source.

As APRSd and APRServe represent the global APRS INTERNET network, and Igates come and go all the time, I am finding myself increasingly confused as to what the real "aprserv" network is.

Each APRSd provides a WEB interface to see what other systems it is connected to, but wouldn't you have to be a worm to crawl through every possible connection to see what the big picture was at any instant?

What would really be neat would be a LIVE WORLD map showing all active IGates, with directional arrows between them showing the types of links.

Am I dreaming? (or is it already done somewhere?)

Since we are SO DEPENDENT on the infrastructure created by Steve and Dale and Brent and Sprouls, and others and our future depends on the reliability of this INTERNET network, I hope that we can come up with this big-picture LIVE INTERNET map as a way of keeping our fingers on the pulse... of the "network"

? de WB4APR, Bob ?

The web status was added in 2.1.3 I believe, many IGates are running
older versions. In addition, when people upgrade they must manually edit
their config file to enable the feature, so many of those who are using
the latest version do not have this enabled.

If you ever do succeed to produce such an image, it would be a horrible
mass of spaghetti, as many IGate are configured in strange and wonderful
ways!

FYI, the aprsd web interface is enabled by default. The sysop must modify his aprsd.conf to disable it. Versions 2.1.2 and up have it.

The real barrier to making the map is the lack of lat/lon info of the aprsd igate in the status page. This could be added but would require one or more new entires in the aprsd.conf file.

Why cannot it capture it from the Igates POSITs?
Or couldnt each APRSd server simply beacon its own POSIT at the same 30
minute interval as everyone else?

If the RF-to-Internet station included it's posit in the
data stream every 30-minutes, and there was a
"band-of-origination" byte in the spec that it could insert
into each posit as it is gated, this would be a very useful
system to plot the APRS' fluid topology.

Of course, this is simply the input from a user, who doesn't
program APRS code, so the compexity of doing such a thing
escapes me. But it would be a useful utility. :o)

If it is a once-every-30-minutes beacon, you may as well include
the frequency, rather than just the band.

I think it is time to make the I-GATE ICON an OVERLAY ICON. This way, we can overlay "6", "2", "H" "S" to represent 6m, 2m, HF and Satellite IGates. I think this will be important in the years to come...

In fact, it is trivial to add this to APRSdos, only by adding a single byte in the list of ICON's that can be overlayed.

As I've said in the past, I still don't see the need to limit overlay to
any set of icons. javAPRS has always supported overlay of any icon.

I agree. The Sprouls had a problem with it initially. Maybe that problem is no longer with us, now that they have been supporting Overlays for some time.

But in general, overlayable Icons need to have enough empty space in the center so that the overlay character looks nice, like it fits, instead of obscuring the central image of the ICON. I think that this is the main reason why we have not opened up Overlays to all characters, and tend to take it on a case-by-case basis...?

Hi...

I tried a few weeks ago to plot the interconnects between APRSd/APRServe...
and ran into a problem... I do not have a tool that can graph 3D
relationships, and the information I was getting was useless without this...

G'Day

This is a hard one, but I think it is more of SPEC than SIG. There now exists software that makes it very easy to gate particular classes of callsigns to RF... This is hard or impossible under APRSd and WinAPRS, as far as I can tell... But is very easy under UI-View.

What we are seeing in Australia is a few stations sending large amounts of data to RF from the internet... For instance ALL european RF stations, or all stations from a particular IGATE in the USA.

The way that software is working is that it transmits the data onto RF as soon as it gets it from the IGATE. The most horrible example of this was when one station connected to an IGATE on the port that had the 30 minute history, and kept transmitting continuously for minutes.

Given for ALOHA we should be utilising the frequency less than 20% should the spec state that no transmitter should transmit on a channel more than 20% over a 30 second window? [720 Bytes/30 seconds]

Now,

- o Is this reasonable?
- o Are other people seeing these sorts of problems?
- o If this were implemented, what should we do with packets over the Quota?
- o Should we delete them
- o or try to send them again once and then delete them?

Please do not mis-understand me... There are certainly good reasons to push data from the internet to RF, and UI-View does a lot of good things for APRS... Some clarification would be useful before too many people start doing too many horrible things to wreck APRS.

Not really, and it certainly can't be done accidentally. It requires the user to edit a file and input the information for the stations he wants to gate. (I thought WinAPRS also had that facility?)

>What we are seeing in Australia is a few stations sending large amounts of
>data to RF from the internet... For instance ALL european RF stations, or
>all stations from a particular IGATE in the USA.

Just as a point of fact, neither of those selections is possible in UI-View.

> o Is this reasonable?

No, and have you told the few stations doing it that it isn't reasonable? If not, why not? If you've told them, what did they say?

Good idea. I like the idea of self-enforcement of the 20% aloha rule in general as a default. The user can override it on a case basis, but after say one hour, the default kicks back in. Or something like that...

Actually, come to think about it, CHANNEL SHARING at less than 10% is totally enforced and built into APRSdos. Always has been. Even for manually transmitted packets, the software will not let you transmit ANY packet any more often than one every 10 seconds. I guess I assumed that this fail-safe protection being built-in was so fundamental to our UI network, that I never thought to suggest to other authors to make sure they also had some kinds of built-in loading protection.

The more I think about it, the more I would hope that all authors include some kinds of default limits on channel loading. I am not saying that you cannot let the user override these defaults. Of course, there are

exceptions and so forth, but in general, it seems reasonable to me that we all must protect the channel from unintended consequences of improper settings by having this final LOADING timer on each stations contribution to the network...

Just a thought. I am not pointing any fingers at all. I do not know what the other authors do, but 10% loading restrictions have always been fundamental to APRSdos to protect the network....

Any other use of the channel should not be on 144.39 but should be on a dedicated frequency...

Below are the aprsd.conf statements that control Internet to RF packet gating. Note TncPktSpacing which controls the rate packets

are allowed to be transmitted on RF. These packets come from a 64 packet fifo queue. Packets overflowing the queue are discarded. The discarded packets are counted in "TncQ Overflows" viewable on the aprsd html status page.

Allow Internet to RF message passing.

rf-allow yes

#

#Set the minimum time between TNC transmit packets in milliseconds

TncPktSpacing 1500

#

#

#Selected call signs which are always gated to RF

#if they are not seen locally. All packets from

#these are gated in real time. Do not use unless

#you really need real time data. Consider posit2rf below.

#They are case sensitive! Use upper case. Up to 64 may be defined.

#

gate2rf K4HG-8 N4NEQ-9

gate2rf W7LUS-14

#

#Call signs of stations whose posits are gated

#to RF every 15 minutes. Only posit packets are

#gated. Posits are taken from the history list.

#They are case sensitive! Use upper case.

posit2rf K4HG-8 N4NEQ-9

posit2rf W7LUS-14

#

#Define a list of message destination call signs or aliases

#to gate to RF full time. Note: the CQGA example

#below is CQ GA (Georgia). Edit to suite your locale.

#Up to 64 of these may be defined. They are case sensitive.

#

msgdest2rf SCOUTS KIDS CQGA

#

#end

APRServe has always had hardcoded limits far, far below this limit, with
one message packet per station every minute, and one position report
every 10 minutes.

Hummh... I can think of some ideas.

1) In the case of multiple packets, then this does not allow multiple packets to be all bundled together into a single multi-frame packet burst? THus we lose the advantage of TXD delay amortization? Actually, it probably does, since multiple packets if they queue up due to a busy channel, then they will all be bundled by the TNC anyway when the channel clears.

2) If 1.5 seconds above is applied to every packet, then we do get the inefficiencies of multiple TXD delays and you also get lots of problems with collisions when the first packet is still being digipeated when the next one comes out. In this case, it is still better to bundle up say 3 to 5 packets at a time before transmitting any of them?

So would it be better to force the IGate-to-RF to BUNDLE packets and then limit the timing of these bundles? Somethign like this:

- * Hold each packet for 3 seconds.
- * Combine each new packet with the pending queue
- * When a total of 5 packets are accumulated OR more than 3 seconds has gone by without any more packets, and when the courtesy count down timer is zero, then transmit them all at once.
- * reset courtesy count-down timer to N seconds.

If the Igate is to be an equal user of the channel, then set N to about 18 seconds. If the Igate is to get priority, then set it to about 8 or less..

Thats good. I like that. But, with over 2000 people on the APRServe stream, and say more than 10 of them decide to communicate with someone in dayton, then that totals to about 11 packets per minute or about the ALOHA limit for the Dayton IGate.

Thus, the limit seems to be a reasonable one, although it could saturate in such a worst case scenario...

Is the Dayton IGate deaf, or if the comparison with ALOHA a bit stretched?

Sorry I wasn't more clear.

Does the Dayton IGate operate in CSMA mode, namely does it listen
before transmitting in order to reduce collisions?

Maybe in time for DCC? That would be nice. I think it's important to get an actual, official Version 1 accomplished as the working group intended. Some of the stuff recently being discussed here could come later.

Hello everyone,

I have written a command line utility that takes arguments and formats them
into a APRS WX packet.

I have some questions about copyrights, luminosity, snowfall, and raw rain count.

1) How do I say that my program sends APRS packets? Can I say it sends APRS(tm) compatible packets? I'm not willing to pay any licensing fees. The program is going to be released into the public domain.

2) The aprs spec (version 101m) isn't very clear about how luminosity is included in the packet. The spec says:
Other parameters that are available on some weather station units include:
"L = luminosity (in watts per square meter) 999 and below.
l l (lower-case letter "L") = luminosity (in watts per square meter)
1000 and above.
(L is inserted in place of one of the rain values).
s = snowfall (in inches) in the last 24 hours.
= raw rain counter"

What does it mean by replacing one of the rain values? Can someone show me an example packet? One with luminosity less than 1000 and a packet where luminosity is over 1000.

3) How many characters long is the snowfall data? s1? s12? s123? s1234?

4) How many characters long is the raw rain counter data? #1? #12? #123? #1234?

Hopefully my questions are not too confusing. I would not be surprised if they are, because I'm terribly confused with the APRS spec.

-James Jefferson KB0THN

Notice:

September 1, 2000 is the last day to receive the special hotel room rate of \$89/night single or double and the pre-registration price for the conference.

ARRL and TAPR 19th Annual
Digital Communications Conference
September 22-24, 2000 - Orlando, Florida

For more information see: <http://www.tapr.org/dcc>

Information

Mark your calendar and start making plans to attend the year's premier event in digital communications. The 19th Annual ARRL and TAPR Digital Communications Conference will be held September 22-24, 2000, in Orlando, Florida - just minutes from the Orlando International Airport.

The ARRL and TAPR Digital Communications Conference is an international forum for radio amateurs in digital communications, networking, and related technologies to meet, publish their work, and present new ideas and techniques for discussion. Presenters and attendees will have the opportunity to exchange ideas and learn about recent hardware and software advances, theories, experimental results, and practical applications. The Digital Communications Conference is not just for the digital expert, but also for digitally oriented amateurs of all levels of experience.

A Conference for the Beginner as well

The conference is not just for the digital expert. As in years past an entire session strand with beginning, intermediate, and advanced presentations on selected topics in digital communications will be offered. Some of the topics will include: APRS, Satellite Communications, TCP/IP, Digital Radio, Spread Spectrum and other introductory topics. Come to the conference and hear these topics presented by the experts!

Area Attractions

The Orlando Florida area is famous for its attractions and vacation spots. Disney World, Universal Studios, and Sea World (just to name a few) are within 15 minutes of the hotel. Shuttle service from the hotel will be available for a small fee. Cape Canaveral and Cocoa Beach are a 30 minute drive East of the hotel.

Symposia, Seminars and Banquet

Two symposia/seminars will be held which allow those with additional time and interest to make the most of the Conference. For those who may have interest in just one symposium or seminar, registration for the conference is not required to attend these activities. This allows maximum flexibility for those who may want to participate during the Digital Communications Conference, but do not have an entire weekend to devote to the event.

The Fourth APRS National Symposium will be held on Friday and will be moderated by Steve Dimse, K4HG (the developer of javAPRS). It will likely include many APRS software authors, such as Bob Bruninga, WB4APR (the father of APRS), Keith Sproul, WU2Z, Mark Sproul, KB2ICI (the developers of MacAPRS and WinAPRS), Brent Hildebrand, KH2Z (the developer of APRSPUS), Mike Musick, N0QBF (developer of PocketAPRS), and other nationally known APRS leaders. Join this group for the afternoon and evening for in-depth discussions and presentations on the current and future status of APRS. This is a unique opportunity to gain insight into this fast-growing digital aspect of amateur operations that combines computers, packet radio, and GPS (Global Positioning System).

On Saturday night the DCC Banquet will be held. A guest speaker will speak after the banquet and a prize drawing will top the evening. The Grand Prize is a Palm VII Personal Digital Assistant and Synergy Systems LLC has donated two M12 development kits and many more.

The Sunday morning seminar will be focused on PIC development, design, and programming. This five-and-a-half hour seminar will focus on the things you need to know now in order to understand and begin to participate in PIC development.

Co-Hosts

The 2000 ARRL and TAPR Digital Communications Conference local co-hosts will be:

Lake Monroe Amateur Radio Society

(<http://www.qsl.net/lmars/>),

Orange County ARES/RACES

(<http://evcom.net/~jvoisin/ares.htm>),

Seminole County ARES/RACES

(<http://www.geocities.com/capecanaveral/launchpad/4773>),

and Orlando Amateur Radio Club

(<http://www.oarc.org/>).

International Co-Hosts PRUG (Packet Radio User Group of Japan) will be the International co-host for a third year running. PRUG will be hosting an informal social Friday evening before their seminar and symposium is held. Visit <http://www.prug.or.jp> for more information about PRUG.

Hotel

Conference presentations, meetings, and seminars will be held at the Orlando Airport Marriott. It is highly recommended that you book your room prior to arriving. A special DCC room rate of \$89/single and \$89/double per night has been blocked for 50 rooms and is available until September 1st, 2000. Once the 50 rooms have been reserved, room rates will increase. So be sure to book your rooms early! The hotel provides transportation to and from the Orlando International Airport. Please contact the hotel to arrange specific transportation needs.

Orlando Airport Marriott (conference hotel)
7499 Augusta Drive
Orlando, FL 32822
Phone 407-851-9000, Fax 407-857-6211
(<http://marriott-hotels.com/MCOAP/>)

What you can expect at DCC 2000

- A full day of papers and breakouts for the beginner to the advanced
- Two seminars/symposiums
- The fifth annual Student Paper session.
- A banquet with Special Guest Speaker.
- Informal get-togethers throughout the weekend.
- TAPR Membership Meeting
- An event at which the most important new developments in amateur digital communications are announced.
- Digital 'movers and shakers' from all over the world in attendance.

There are few activities where your participation can be so much fun and important! What a great way to share and renew your enthusiasm for digital amateur radio! A get-together with colleagues and bringing each other up to date on your latest work -- all this, and more, for an unforgettable weekend of amateur radio and digital communications. We hope to see you at the ARRL and TAPR Digital Communications Conference on September 22-24, 2000!

Full information on the conference and hotel information can be obtained by contacting:

Tucson Amateur Packet Radio
Phone: (940) 383-0000.
Fax: (940) 566-2544
Email: tapr@tapr.org

Sender: bounce-aprsspec-11589@lists.tapr.org
Precedence: bulk

I'm happy (you don't know *how* happy) to announce that APRS Protocol Specification Version 1.0 was approved by the APRS Working Group on August 29, 2000 and has been made available for download at the Working Group web page, <http://www.tapr.org/tapr/html/Faprswg.html>.

This Version 1.0 (technically, due to change control, version 1.0.1) document is nearly 130 pages long and does a tremendous job documenting the APRS protocol as used on the air in the summer of 2000. We should all thank the Working Group members, and especially Ian Wade, G3NRW, the Technical Editor who actually wrote the thing, for their hard work. Although the process took far longer than anyone anticipated when we started, I think the end result is definitely worth the wait.

Where do we go from here? Although this is an excellent document, it almost certainly still contains errors, omissions, and ambiguities. In addition, it reflects only the current protocol, and not any of the areas in which the protocol might be extended. The WG members will be meeting at the DCC in Orlando next month and electronically thereafter to put in place a mechanism to deal with requested corrections and enhancements. The WG Charter outlines a way to handle this, but experience has shown that some modifications may be necessary for a workable process.

Also at the DCC and thereafter, the WG will consider adding new members. Since its founding, several new authors have come on the scene, and two of the original members have resigned. Any author of software or firmware implementing the APRS protocol who wishes to join the WG should contact me (jra@febo.com or n8ur@tapr.org) directly. Please -- we need to hear directly from those interested in joining, so rather than writing to ask that someone be considered, encourage that person to get in touch with me. Also, please remember that the WG is not affiliated with TAPR. Membership decisions will be made by the group, and I can't tell you now how many (if any) new members will be added.

73,
John Ackermann N8UR

First, congratulations to the WG for completing the approval of the =
Protocol Spec! I am sure you all worked very hard to document this =
wonderful system/service!

The recent Internet Routing debate inspired me to read the WG charter =
and to begin wading through the Spec in order to learn more about APRS. =
I have learned a lot from both the discussion and the reading.

It seems that implementing NOGATE (or whatever is used) is a protocol =
question. =20

My first question would be is that correct? Is implementing NOGATE (or =
whatever) a change to the protocol? If it is not then why?

Again, I ask, not to stir the pot (which is why I am asking here), but =
for my own education and understanding. If it is a protocol question, =
then the charter seems to outline a process for implementation. I am a =
bit confused since it sounds like NOGATE is being implemented already.=20

Thanks in advance for helping me to learn more about this great system!

Peace and 73,
Stephen
KD30G

Hi All-

Nice Job on the Spec!

In Chapter 12, page 67-- the minimum central pressure is defined as 4 digits. The present on-the-air protocol is 3 digits. If we are changing to this-- can a time table be set?

Now that Version 1 is out - is there a mechanism for adding to the protocol?
I have 17 months of suggestions built up.

73 de kg5qd Dale

We basically got little input from any of the authors either way. So my
guess is that you know more about what all the authors do with this field
and it is best to discuss it with any author that might be doing it
differently.

> Now that Version 1 is out - is there a mechanism for adding to the protocol?

Yes, submit it to the WG. The process is painful, but I hope we will
make progress...

Bob

<snip>

Great work, men! It's rewarding to see a "group" actually get things DONE!
Congratulations on a fine document. You should all be very proud of your
accomplishment. I know it wasn't easy. Thank you for your effort and
perseverance.

Now, on to version 2. hi hi

Hello, Folks.

Great Work on the Specification. Its been a long time coming, and badly needed. Sure, its not perfect, but I have never yet seen a cooperatively produced spec that is. Well, come to think of it, I've never seen a unilaterally produced "perfect spec" either!

I need to generate a suite of validation packets for testing the code I am writing. I have in mind something along the line of Ian's "Mic-E Test Suite" he distributed on Aug 2, 2000.

If I am going to do that work, it might as well be done in a form that is usable by others. So, the question of format comes up.

(a) Can everyone handle text with only carriage-return line delimiters, or does it have to be CR+LF? What about Unix line delimiters?

(b) My code will reject "packets" from file-read input that begin with anything other than a number or upper-case A-Z (ie, first character of a call-sign). Its easy to start lines with something else, say "/" (as a

random choice) as a comment, describing what the packet is testing. Does anyone else's code have this or similar capability? If not, how should packets be tagged so as simplify cross-reference between the packets and the description? Another option would be to produce two files, one containing only the test packets and the other with the same test packets plus comments. It would then be up to the tester to correlate the text with comments to the action of the code.

(c) Are there naming requirements to allow the text file to function as a source of "packets"? Of course, a text file can always be renamed.

(d) Are there any other requirements I should be aware of?

I plan to use sample packets directly from the spec for validation of acceptance and interpretation.

I also plan to include packets with a variety of errors and problems to test handling of fault cases. But, there will be no cases which violate the constraints of AX.25 packets. That means, for example,

(1) NO packets with excessively long call signs (ie, W7ABCDEF), either as source address or as via-calls.

(2) NO packets with SSID's outside of the range 0-15 (ie, KA7EHK-99), either as source address or as via-calls.

(3) NO packets with excessively long destination address (ie, APW345678)

(4) NO packets which exceed the AX.25 character-length limits

If anyone has suggestions for common fault-types (especially as seen on the air), they are encouraged to write me. Rather than clogging the list, unless your comment really needs to be seen by other list readers, please send your comments directly to me.

Cheers, everyone,

Jim Wagner

Hi Jim. Take a look at my <APRSdec> program (<http://www.tapr.org/~g3nrw>).
You'll find many error traps in there.

(This message is posted on the APRS SPEC SIG on a monthly basis.)

PURPOSE

The purpose of the APRS SPEC SIG is to provide a forum for folks interested in discussing the APRS protocol specification.

POSTING MESSAGES

To post messages to the APRS SPEC SIG, send email to aprsspec@lists.tapr.org

APRS SPEC SIG RULES

The APRS SPEC SIG has a few simple rules:

- . Be courteous. Abusive, insulting, or rude behavior demonstrated towards another list member is a violation of this rule.
- . Stick to the subject, i.e., the APRS protocol specification. Subjects that are only tangentially related to the APRS protocol specification (like "what kind of printer should I buy to print out my copy of the APRS specification?") may be considered off-topic. If you start a message with "this is off-topic..." then you are violating this rule.
- . Be succinct when composing a message. (The APRS SPEC SIG software has been optioned to limit the length of each message.)
- . When quoting a previous message, only quote the parts of that message you are referencing. (The APRS SPEC SIG software has been optioned to limit the length of a quote.)
- . Do not send messages in HTML format.
- . Do not send attachments.
- . Cross-posting is not permitted. (The APRS SPEC SIG software has been optioned to prevent cross-posting.)

. The APRS SPEC SIG administrator reserves the right to suspend or ban any list member who violates these rules.

UNSUBSCRIBING

To unsubscribe from the APRS SPEC SIG, follow the directions you will find at the bottom of each message you receive from the APRS SPEC.

QUESTIONS, COMMENTS, ETC.

If you have any questions, comments, etc. concerning the APRS SPEC, please email the APRS SPEC SIG administrator at the address below.

Stan Horzepa, WA1LOU, wallou@tapr.org

It would probably be useful though, to create a file containing such errors
as a separate item.

(I am volunteering to help)

Point being, there are devices like HSPs out there, that give you the
ability to get data in your serial port that could never be transmitted
over the air.

Testing compliance with a spec is one issue, but as we've seen with WAPRS,
bad data must not cause failures.

This might be simpler to implement with a program though.
Define error routines, then activate each either randomly, or just walk the
tree choosing all possible error combinations. I did this once in the
credit terminal world, to fish out a bug that only affected some of our
terminals, very infrequently. With a randomized error spectrum, it was 5 in
7000. Once I found that, I was able to repeat it every time, because I
knew the mechanism from the program logs.

Testing for crash could even be automated, since you could stimulate a
response from the target software to see if it's still alive (?APRS? or
similar)

I believe that the APRServe data stream considers a line starting with the
"#" character to be a comment.

So does Perl, which I use a lot to process APRS packets off the internet
data stream.

19th Annual ARRL/TAPR Digital Communications Conference

Orlando, FL ñ September 22-24, 2000

** Update 9/11/2000 **

A little more than one week away, the 19th Annual ARRL/TAPR Digital Communications Conference is about to begin. For detailed information about the conference, please visit the official DCC web page at <http://www.tapr.org/dcc>.

Registration for the conference will be taken at the door. Friday registration is for an entire afternoon APRS activities, demonstrations, and

presentations. Saturday registration includes conference proceedings, lunch, and a full day of presentations. Saturday night includes Banquet, dinner speaker, and prize drawing. Sunday registration is for the PICmicro Design seminar.

Banquet Prize Drawings:

Grand Prize ñ Kenwood TM-D700A (donated by Kenwood)

2nd Grand Prize ñ Palm VII Personal Digital Assistant

Two Motorola Oncore M12 GPS Evaluation Kits (donated by Synergy Systems, LLC)

Map and coordinates:

A map of the conference hotel and coordinates are available at
<ftp://ftp.tapr.org/dcc/dcc.hotel.map.pdf>

Speakers:

The following is a list of presenters. Preliminary schedule is available from <ftp://ftp.tapr.org/dcc/2000.dcc.schedule.pdf>

APRS Seminar - Friday September 22, 2000

John Ackerman, N9UR	APRS WG
Steve Bible, N7HPR	T-238 Weather Station
John Blowsky, KB2SCS	APRS LOOKUP
Steve Bragg, KA9MVA	HamHud
Bob Bruninga, WB4APR	APRSdos, satellite, etc.
Steve Dimse, K4HG	Internet APRS
Walter Dunckel, KD6VYV	Serial Control of D7/D700
John Hansen, W2FS	KISS TNC, D700 Keyboard
Dale Huguley, KG5QD	Weather Server
Larry Gahagan, AB0JM	Wildfire Support
Byon Garranrant, N6BG	TinyTrack
Mike Musick, N0QBF	PalmAPRS/Tracker construction
Robert Osband, N4SCY	Public Service with APRS
Tom Schaefer, NY4I	APRS Email Gateway
Darryl Smith, VK2TDS	APRS in the 2000 Olympics
The Sprouls, WU2Z/KB2ICI	Mac/Win/XAPRS
Rob Wittner, KZ5RW	APRS-CE

Main Session, Paper Presentation - Saturday 23, 2000

Titles and abstracts are available at
<http://www.tapr.org/tapr/html/Fcnc19.html>

Sorry if this is an old question. A quick search of the archive and the spec did not provide an answer.

The source for my weather data provides two different barometric pressures. One is absolute and one is adjusted for our local altitude (over 5000 feet here). Which one is customarily encoded into an APRS packet?

Thanks in advance

-Mike, K5ATM

Subject: Final Update - DCC Orlando, FL Sep 22-24, 2000

19th Annual ARRL/TAPR Digital Communications Conference
Orlando, FL - September 22-24, 2000

**** Final Update 9/18/2000 ****

Counting down the final days until the 19th Annual ARRL/TAPR Digital Communications Conference this weekend in Orlando, Florida. For detailed information about the conference, please visit the official DCC web page at <http://www.tapr.org/dcc>.

Registration for the conference will be taken at the door. Friday registration is for an entire afternoon APRS activities, demonstrations, and presentations. Saturday registration includes conference proceedings, lunch, and a full day of presentations. Saturday night includes Banquet, dinner speaker, and prize drawing. Sunday registration is for the PICmicro Design seminar.

DCC Social:
Please join us Friday evening at 7:00 PM for a social get together time. The social is generously hosted by the Packet Radio Users Group of Japan (PRUG).

PRUG Presentation:
Friday night the Packet Radio Users Group of Japan will present talks on

their progress on high-speed digital networks in Japan.

Saturday Night Banquet Speaker:

Mr. Doug Campbell, of Triton Network Systems (<http://www.triton-network.com>)

will be our DCC Banquet Speaker. Triton Network Systems is located in Orlando, Florida.

Vice President Product Management, Marketing, & International Business as Vice President of International Sales, Marketing and Product Management, Mr.

Campbell leads the assessment of global community needs and spearheads the development of Triton Network Systems' product and marketing strategies.

Mr. Campbell cultivated his management skills in sales, marketing and product development working 17 years for Nortel Networks. While based in Singapore, he built a multifunctional pan-Asian team, which successfully captured a 100% market share with MCI-WorldCom Asia, successfully introducing a number of new products. Prior to this, Mr. Campbell was instrumental in the establishment of an SDH broadband equipment joint venture in China and served as a member of the company's Board of Directors.

Mr. Campbell received a Bachelor of Engineering Physics degree from the Royal Military College of Canada in Kingston, Canada, and a Master of Business Administration from IMD (University of Lausanne) in Switzerland.

Banquet Prize Drawings:

Grand Prize - Kenwood TM-D700A (donated by Kenwood)

2nd Grand Prize - Palm VII Personal Digital Assistant (donated by TAPR)

Two Motorola Oncore M12 GPS Evaluation Kits (donated by Synergy Systems, LLC)

Microchip PICSTART-PLUS PICmicro Programmer (donated by Microchip)

PIC Seminar Prize Drawing

Microchip MPLAB-ICD (donated by Microchip)

Project and Demonstration Room:

The DCC is a place where people can talk about their projects and gain ideas

for new ones. The Project and Demonstration Room has become a recent DCC tradition where people can bring and display their projects. The room will be located next to the registration room and across the hall from the main presentation room. The Project and Demonstration Room will open at registration time and be closed (locked) 11:00 PM Friday and Saturday night.

Map and coordinates:

A map of the conference hotel and coordinates are available at
<ftp://ftp.tapr.org/dcc/2000.dcc.hotel.map.pdf>

Speakers:

The following is a list of presenters. PDF version available from
<ftp://ftp.tapr.org/dcc/2000.dcc.speakers.pdf>

Speaking schedule (subject to change) is available from
<ftp://ftp.tapr.org/dcc/2000.dcc.schedule.pdf>

(This message is posted on the APRS SPEC SIG on a monthly basis.)

PURPOSE

The purpose of the APRS SPEC SIG is to provide a forum for folks interested in discussing the APRS protocol specification.

POSTING MESSAGES

To post messages to the APRS SPEC SIG, send email to aprsspec@lists.tapr.org

APRS SPEC SIG RULES

The APRS SPEC SIG has a few simple rules:

- . Be courteous. Abusive, insulting, or rude behavior demonstrated towards another list member is a violation of this rule.
- . Stick to the subject, i.e., the APRS protocol specification. Subjects that are only tangentially related to the APRS protocol specification (like "what kind of printer should I buy to print out my copy of the APRS specification?") may be considered off-topic. If you start a message with

"this is off-topic" then you are violating this rule.

- . Be succinct when composing a message. (The APRS SPEC SIG software has been optioned to limit the length of each message.)

Hello, group,

Well, here is the first in what should become a test suite for APRS code writers. This one isn't the most critical ... it provides a multitude of STATUS packes with various valid and invalid call signs. If you don't do any call validation, then don't bother. But, if you reject calls like TAH0E (thats a zero) or WAB97C, then use this to test your call filter. There are about 15 valid calls (each including no SSID, one digit SSID, and two digit SSID). And, there are about 100 additional invalid calls. They are systematic order.

The file includes comment lines. The "//" is used as the first two characters of every comment and this is the only place this pair appears. To change it to other comment tokens, simply do a search-and-replace to change to your appropriate comment character(s).

A very extensive test for the destination field comes next.

You can find the file at:

<http://i6.yimg.com/6/6c78a2c3/h/ac890c30/calls.txt>

Hello, group -

Your comments are solicited.

Today, the following two packets were received.

KB7ILD-9>GPSLK,W7VHY-10*,WIDE5-1:\$GPRMC,220306,A,4736.8947,N,12219.4088,W,000.0,000.0,011000,018.8,E*69

KD7NM-9>GPSMV,W7AA-10*,WIDE5-3:\$GPRMC,220342,A,4745.988,N,12220.638,W,000.0,357.2,011000,018.9,E*67

I think we all know what they are SUPPOSED to indicated, but don't. As a refresher, here is the text from the spec...

=====
AX.25 Destination Address

Where it is not possible to include a symbol in the Information field, the symbol may be specified in the AX.25 Destination Address instead, using the following generic destination addresses: GPSxyz, GPSCnn, GPSEnn,

SPCxyz and SYMxyz.

The characters xy and nn refer to entries in the APRS Symbol Tables. For example, from the Primary Symbol Table, a tracker could use the Destination Address GPSPVV V or GPS30 to specify a "car" icon.

The character z specifies the overlay character (where permitted), or is a V V (space) - the space is a filler character, as all AX.25 addresses must be exactly 6 characters long.

=====

Note, particularly, that last sentence. How do we handle destination addresses which are NOT 6 characters long?

- (1) Do we assume that a space was intended?
- (2) Do we reject it as an invalid APRS packet?
- (3) Do we accept it as an APRS packet, but do not process the destination address to be anything other than a non-symbol encoding character sequence?

Many thanks,

Jim Wagner

What is wrong with the above? The TO fields are perfectly valid APRS TO fields.

Brent KH2Z

The Z in GPSxyz is optional. Not required. Trailing spaces are ignored. Remember that your FROM in the AX.25 is also 6 characters. A callsign like KH2Z is padded with 2 trailing spaces. They are then ignored on receive.

I amend what I said, no timestamped APRS status packets, which basically invalidates my previous statement. But note, there is no restriction that a callsign needs to be a valid Amateur Radio callsign. Thus, the example TAH0E is perfectly valid. It just is not an Amateur Radio callsign.

[snip]

I thought the source address of an APRS frame could be anything that is a valid AX25 address as defined in the AX25 spec. For example, don't remote digis and other such devices sometimes use descriptive addresses that wouldn't validate under normal callsign rules?

I'm not sure i understand the practicality of filtering out non-valid HAM calls in APRS. Many real-applications of APRS use tactical calls to avoid confusion out in the field. SUch a filter may be a nice option, though I don't know who would use it, because sometimes the only thing interesting to watch is the special events. Or am I missing something?

All callsigns in AX.25 are 7 bytes long, no matter how many characters are used. The ADDRESS field is fixed length. Most TNC's may truncate the call if less characters are used, but they are all transmitted as spaces.

Hello, List ...

Both Bob Bruninga and Brent Hildebrand pointed out that many TNCs do not display terminating spaces in the Destination Address field, just as they do not display terminating spaces in the From Address field.

This observation leads to the very slightly picky observation about the paragraph in the specs reading:

> The character z specifies the overlay character (where permitted), or is
> a " "
> (space) - the space is a filler character, as all AX.25 addresses must be
> exactly 6 characters long.

The same requirment is not stated for the From Call, it is automatically fulfilled by the TNC. Yet, with the preceeding statement, it is easy to believe that the Destination Address to be parsed by the software will have, in this case, exactly 6 characters, just like the addresss field of a message will have exactly 9 characters.

Now I know better and my code will reflect this fact.

Many thanks to both Brent and Bob...

Hello, List....

Bob Bruninga and Brent Hildebrand have just pointed out that (at least some) APRS programs do no call filtering because of several reasons including:

(1) Commercial application

(2) FCC regulations does not require "real" calls in the From Field of a packet, thus allowing "tactical calls" such as RED3.

This test file is not required to be used by anyone. If you don't do call filtering, then don't bother with it. But, if you do, its available.

For me, personally, I have no interest in commercial application and will reject any request for commercial licensing.

As for the second point, what FCC regs allows does not make it right. I find no justification for hams, especially using packet, to use anything other than their real call. Special events can be handled by SPCL in the destination field. But, I had best stop before the flames from my nostrils melt my keypad!

The test file does have one potential problem - it does not contain CRLF line terminators; there are only CRs. It will be replaced with one containing CRLFs. If you wish to use it, it is at

<http://i6.yimg.com/6/6c78a2c3/h/ac890c30/calls.txt>

If you don't, please just forget about it. There will be a second one shortly providing a very extensive test of non-MicE destination address fields. That will be followed by a short file to test discrimination of local vs digipeated packets.

Depending on their sizes, there will be several to quite a few following that to test parsing of the different types of APRS packets.

Cheers,
Jim, KA7EHK

I think you might be missing how Tactical calls are used at APRS special
events to eliminate confusion and ambiguity on maps. Commonly used
tactical calls in my area are:

LEAD, TAIL, VIP1, VIP2, VIPn ...
CHASE1, CHASE2... CHASEn
SAG1, SAG2,... SAGn
H2O, RANGER, MEDIC1, MEDIC2, ...

These assure that there is no mistake in identification of an object on the maps. They follow the FCC rules by including the HAM call in the BText every 10 minutes.

Jim,

There might be reasons other than "commercial" applications. Aside from the basic tactical type calls already mentioned, you might want to consider non-profit or disaster relief organizations when making rules. Other organizations often use tactical calls for all communications, and there's a lot of non-FCC organizations that don't even use the 6 letter calls. Red Cross, Civil Air Patrol, MARS are a few examples of organizations that most software authors have given access to their programs because of their benevolent nature.

Callsign restriction adds a level of complexity that just really isn't needed. If I just had to do some filtering, I'd probably go for NOCALL and that's about it.

Ed Woodrick

On Mon, 2 Oct 2000, Jim Wagner wrote concerning APRS callsigns:

> As for the second point, what FCC regs allows does not make it right. I
> find no justification for hams, especially using packet, to use anything
> other than their real call. Special events can be handled by SPCL in the
> destination field. But, I had best stop before the flames from my nostrils
> melt my keypad!

I'll melt my keypad a little ;-)

Search & Rescue:

AIR1, AIR2 (Helicopters)
TEAM1, TEAM2 (Ground teams)
DOG7, DOG8 (Search dog teams)
R50, R51 (Vehicles)
BASE (Command center for the search)

In each case above, we use the same tactical call on APRS as their radio tactical call. This matches the white boards we use to keep track of status for each team. The radios we use for voice are on a county search frequency, so tactical calls are ok there. APRS used is on amateur frequencies.

Tactical callsigns are critical in reducing the confusion factor. Things get confusing in a hurry if we must translate from

callsign/SSID to radio tactical callsigns at the point when an injured person is found (the busiest/most confusing part of the operation). KISS principle in real life here. Seconds really do count.

The sheriff himself looks at the map at times, and doesn't understand or care to understand callsigns/SSID's. He wants to know instantly where each team is.

In this case (support of a search operation) callsigns are of secondary importance. The more hidden they are from logistics and operations people, the better. I set them up to broadcast just enough to keep it legal and no more. The APRS software will show only the tactical callsigns on the topo maps. The hams running the APRS station can determine callsigns if/when necessary.

Page 45 of the APRS Protocol Reference provides a table for Mic-E longitude Degrees Encoding.

If we have already determined the offset from the Destination address, what is the purpose of displaying the Long Offset in the table? (+100/+0)

Won't (D-28) + Offset work in all cases?

ARGH!!!!!!! I just checked the spec, and it is wrong about grid squares.. We worked long and hard to get everyone on the same page with regard to this new format for GRID SQUARES. But now I see that the implementation of the wording in the spec, put it in the wrong place. Of course it is entirely my fault for not finding this prior to publication...

It is under the MIC-E heading and this is completely incorrect. It has nothing to do with the Mic-E. It was supposed to replace the "MAIDENHEAD" section on page 33. It has nothing to do with the Mic-E on page 55!

No wonder everyone is confused... ARGH...

The preferred format for GRID SQUARES is >GG##GG/\$...

The reason for this is because it *can be received on a THD7 or D700* and because it permits the inclusion of ICONS which the older [GG##GG] did not. Maps without ICONS are quite uninteresting... Mobiles and HT's that cannot receive grids are also a disadvantage...

I don't know what we do officially about this mixup, but everyone with a THD7 or D700 would probably prefer that grid reports be in this format so they can receive them and not be left in the dark... Unfortunately, they will not be "decoded" as an actual posit, but they will be "received". The [] format will not even be received...

For backwards compatibiliy, I will put the [GG##gg] format back into APRSdos for the upcoming Meteor Shower activities. But it will leave out everyone that could try a new first.... Moible or HT MS!

Hey Bob, don't get upset, Grid Squares are hard to understand sometimes. Let me tell you a funny story, time out from APRS for a sec.....

When I was wild a crazy and in the Marine Corps, I was stationed on the island of Okinawa, Japan. One of the things that we always enjoyed doing to break up the monotony, was to send a new Marine on an impossible mission. Such as sending a guy over to the supply depot to get a BA-1100-November with a ST-Ring attached. Translation, a BALLOON AND STRING!

Well, the best was one day we sent a poor feller over to supply to get a Box of Grid Squares. When he left we called ahead and told them to tell him they'd just run out, but they knew another area supply to go get them. Well, to make a long story short, the poor guy ended up carrying a box on his

shoulder all the way across the small base we were at with the words, GRID SQUARES, on it! It took him a long time to live that one down!

So, when your over there kicking your toe against the desk, think that you made a big mistake, just think about how embarrassing it really could be!

Good Day!

73,
Scott

OK, I was wrong and confused as well by the (now) 3 different references to the GRID-SQUARE Format. So I guess it is OK as written, but misleading. I would have preferred that the page 33 reference INCLUDE the >GG##gg/\$ format as well with the note that it is the only grid format receivable by the Kenwoods...

The following comment occurs on page 64 of the spec in the "Positionless Weather Data" section:-

"Note: The weather report must include at least the MDHM date/timestamp, wind direction, wind speed, gust and temperature, but the remaining parameters may be in a different order (or may not even exist)."

The way the spec is written, that comment appears to only apply to "Position Weather Reports", but is it in fact also supposed to apply to "Complete Weather Reports"?

The reason I ask is that it has been reported to me that the Kenwood radios appear not to recognise a "Complete Weather Report" unless it contains a gust value. Without the gust value they regard it as being a mobile station. (Note - I haven't verified this myself, because I don't own a Kenwood.)

Yes, in general, in order to ignore all the WinAPRS WX stations that are sending weatherless positions, the presence of the "t" and "g" are used as verifiers of weather data included within a "complete" wx report.

[snip to keep the list server happy]
>Yes, in general, in order to ignore all the WinAPRS WX stations that are
>sending weatherless positions, the presence of the "t" and "g" are used as
>verifiers of weather data included within a "complete" wx report.

I could appreciate that, except that only the Kenwood radios seem to be
ignoring it. The format of the beacons in question is:-

=5258.24N/00002.76W_000/000t050r000P035h93b09750

I'm *told* that the Kenwoods regard that as being a mobile station, and
ignore the weather data. (DOS APRS and WinAPRS both regard it as a wx
station, and interpret the data as a wx report.)

However, I was really asking about what that section of the spec is
supposed to be saying. If it is supposed to be saying that the 'g' and
't' requirement applies to "Complete Weather Reports", then, to me, the
way it is currently worded doesn't say that, because the requirement is
embedded in "Positionless Weather Data" inside "Positionless Weather
Reports".

I asked the question because, at the moment, I suppress the gust field
in the weather report if the wind speed is zero. I was quite surprised
to be told that the Kenwood radios don't regard such reports as being
weather data. I then looked at the spec, and concluded that what I was

doing was ok...

Yes, it is because of this ambiguity that we put that statement in the spec. Prior to such a spec, we all had our own little tricks for determining if the WinAPRS packet had valid WX data or not. Most of us still probably use whatever code we already had. Kenwood requires the "g" and the "t" as we meant to codify in the spec. APRSdos requires either a "g" *or* a "t". In any case, the best way to assure its valid WX is to require both the "t" and the "g" in the right places...

Yes, it should apply to both. That should be fixed in the next version...

Hi to all,

I've been running my server for a little while and looking at the packets that are being refused, many of them are preceded by the "cmd:" string and then a valid packet (after a quick look at the following packet).

Would it be sound to remove the leading "cmd:" string in front of a packet, then retreat the packet to see if it's valid or still reject it because it is bad.....

Thanks in advance

The tracker I am developing seems to work -- but not with a D7(a)g in APRS mode.

The packet format is a simple "no timestamp lat/long position report" (second page of chapter 8 -- page 32 of draft 1.0.1m) with course/speed in the data extension.

Packet transmission seems to be OK (i.e. bit timing, X-25 format, etc) since the packet gets through the D7 just fine when the TNC is put in packet mode and my local DIGI repeats the packet.

The APRS data seems to be formatted correctly since APRS+SA is happy with what comes out of the D7 (in packet mode) and I show up on findu.com.

The only problem seems to be the D7 ignoring the packet when the TNC is in APRS mode. This makes me think the D7 is expecting a different APRS data message syntax -- or maybe does not support this type of report.

Before I go into "try stuff until it works" mode I thought I would see if anyone knows if there is an FAQ or a compilation of D7 caveats and what the D7 does and does not support.

Thanks in advance.

Interesting...

The same is happening to me. I developed a WX APRS station, that you connect
direct to the radio. Completely autonomous.

The IGate's recognize, the users recognize, the D7 in TNC mode recognizes,
but when you change the D7 to APRS it doesnt hear nothing.

I thought i was having any glitch with my code. Perhaps there are some bits
swapped, that D7 doesnt recognize.

Interesting to know that finally someone stucked in the same problem.

Cheers!

>Bruno wrote:

>Just out of curiosity, what software are you writing ?

I am writing a windows based tracking/mapping program. The current windows based programs just don't work the way I would like them to, or have quirks that make them a pain to use. I figured I could spend my time griping, or write something I like.

Our local amateur radio club supports the annual MS-150 bike-a-thon (Multiple Sclerosis), SkyWarn, and other events and I wanted something better suited for "real time" asset tracking. I actually wrote a utility for one of the popular programs to refresh the screen every 3 seconds because we couldn't figure out which parameter or configuration setting to change to eliminate "vapor" trails. I wanted something that...

- Supported readily available maps in VECTOR based formats
- Movement in "real time", no vapor trails, object permanence is adjustable
- Map features, map layers and labels easily added or removed
- True 32 Bit Windows program with all the gadgets I normally expect; right click etc.

Because I don't have DOS memory constraints there are no significant limitations on the number of points or labels in a single DOS map. "Objects" move without leaving trails and the maps can be resized or zoomed easily. Additional label points can be added without a problem. Long way to go, but making progress...

Now if I could just come up with all those darn icons...

Regards,

Rich - Wn0x

P.S. The issue I had with the "cmd:cmd:cmd:cmd:" is that I wasn't checking for this possibility and my line parser was trying to treat it as an object.

So here is the output from my TNC:

K5ATM>SOTT10,WIDE3-3:!3505.52N\10628.95W\$000/000

I did a little "try stuff until it works" last night and found if I change the destination address (used as a software version number) from SOTT10 to

something more familiar -- APS199 -- and the D7 was quite happy! I got a beep and my packet was entered on the message list.

Went back and looked at the protocol again and did not see any reason why a software version number of the form SOTT10 would be a bad idea. I did notice that all the software version number examples in the protocol document started with the letter "A" so I changed SOTT10 to AOTT10. The D7 still did not accept the packet in APRS mode.

So, it looks like the D7 is using information in the destination address to decide if a packet is a legal APRS packet -- and APS199 passes the test but SOTT10 does not. What am I missing?

Thanks for any help.

Show us the packet and we can tell in a jiff.

"a packet is worth a thousand words"...

Anyone with any experience with WAP or HDML3? I just got a sprint PCS and want to add support to findu, but the developers docs seem needlessly dense for my application. All I need to start is the markup for a simple text page.

Mike,

I have noticed what you described too. I have found apk001 to work okay, I think. I would have expected Kenwood to fix this in the G version, but I guess they did not.

It isn't a bug, see page 23 of the spec, AP* is a supported prefix, A* is not...

Steve, Bob -- thanks

In hindsight it all makes sense. For what it is worth, here is how I got lost. Maybe the info will be useful in a future version of the protocol document.

Chapter 4 describes the Destination address. The first section gives a list

of 5 types of destination call signs. One is a generic APRS call sign (which are listed in the next section) and one is an APRS software version number. I read this as a list of independent categories -- not that some were subsets of the others. That is, I did not make the association that a software version number was a type of generic call sign -- specifically the AP* generic call sign. I think, in fact, there are really 3 types of destination call signs -- Generic, Mic-E, and ALTNET with the caveat that Generic has three sub types -- with a symbol, without a symbol, and software version number.

This thinking was reinforced by the fact that there is a section on generic APRS callsigns and a separate section on APRS Software Version Numbers with no linkage between them. The fact that AP* is the generic destination callsign used for software version numbers is implicit with the examples but an explicit statement to that effect would have saved me.

Finally, the section on Alternate Net Callsign states that any other callsign not included in the specific generic list or the other categories mentioned above may be used in Alternate Nets. When I read this I assumed that my SOTT10 call sign was not a generic APRS callsign but WAS one of the other categories mentioned above -- specifically a software version number. However, if I had stopped to think how one would implement a system it would have been obvious that it would be impossible to tell the difference between my interpretation of a software version number and an alternate net callsign.

So like I said, it all makes sense in hindsight and I appreciate the education. It seems like others have run into the same problem so I wonder if others followed the same path. If so, I would like to suggest that in some future release of the protocol spec that the use of AP* be explicitly stated. This could be a short sentence below the table of generic callsigns where callsigns like DGPS are explicitly mentioned. Another possibility would be to add a sentence to the paragraph before the software version number examples -- i.e. add "The generic destination callsign AP* is used to specify software version numbers" before the sentence "The following software version types are reserved ..."

I wonder if short descriptions of the other generic call signs should also be included. Some are obvious (at least to me) -- like WX*. Others are not so obvious.

Thanks again

73

It aint broke. The TO ADDRESS is limited to specific addresses according
to the SPEC. Software version numbers beginning with AP are OK. Other
callsigns beginnning with anything else are supposed to be ignored except
for a few BEACON type exceptions.

Except that every Mic-E packet violates the ALTNET spec.

If you have a phone that does HDML 3.0, try this:

<http://www.findu.com/cgi-bin/wap.cgi/?k4hg-8>

I've tried this on my Motorola Star-Tac, and on a simulator for most of the WAP phones, but I'd love to hear reports of how your phone works.

Steve K4HG

(could someone forward this to aprssig for me?)

Done Steve,

Mmm - maybe we aught sign up a volunteer "Official Forwarder" for you,
eh?

(This message is posted on the APRS SPEC SIG on a monthly basis.)

PURPOSE

The purpose of the APRS SPEC SIG is to provide a forum for folks interested in discussing the APRS protocol specification.

POSTING MESSAGES

To post messages to the APRS SPEC SIG, send email to aprsspec@lists.tapr.org

APRS SPEC SIG RULES

The APRS SPEC SIG has a few simple rules:

- . Be courteous. Abusive, insulting, or rude behavior demonstrated towards another list member is a violation of this rule.
- . Stick to the subject, i.e., the APRS protocol specification. Subjects that are only tangentially related to the APRS protocol specification (like "what kind of printer should I buy to print out my copy of the APRS specification?") may be considered off-topic. If you start a message with "this is off-topic..." then you are violating this rule.
- . Be succinct when composing a message. (The APRS SPEC SIG software has been optioned to limit the length of each message.)
- . When quoting a previous message, only quote the parts of that message you are referencing. (The APRS SPEC SIG software has been optioned to limit the length of a quote.)
- . Do not send messages in HTML or Rich Text format.
- . Do not send attachments.
- . Cross-posting is not permitted. (The APRS SPEC SIG software has been optioned to prevent cross-posting.)
- . The APRS SPEC SIG administrator reserves the right to suspend or ban any list member who violates these rules.

UNSUBSCRIBING

To unsubscribe from the APRS SPEC SIG, follow the directions you will find at the bottom of each message you receive from the APRS SPEC.

QUESTIONS, COMMENTS, ETC.

If you have any questions, comments, etc. concerning the APRS SPEC, please email the APRS SPEC SIG administrator at the address below.

In order to decrease the amount of (painful) text entry into the phones,
I've set up a new virtual server strictly for WAP access, with a more
direct URL. To access the find cgi:

wap.findu.com/find?k4hg-8

I have the weather cgi online as well now:

wap.findu.com/wx?k4hg

I plan on porting over all the findu cgis (at least those that make sense
for phone access) eventually. Suggestions are welcome...

Steve K4HG

And as always, can someone forward this to the aprssig?

- Does anyone know if the icons for the symbol lists are available anywhere? I would rather not duplicate them if I don't have to, but don't want any copyright issues associated with "borrowing" them from existing APRS applications.

- Does anyone know where I can get documentation on the NMEA 0183 sentence specifications? I have the Mic-E, Positional and Compressed formats working, but need to add the \$G formats.

Thanks,

Rich Beckwith - Wn0x

After reviewing a lot of logs, the "truck", "car", "jeep", "weather" and "digi" icons come up the most, but there are many more to go after that. Seems a waste of time to re-create them, especially since most folks are used to seeing a particular icon.

Thanks for the GPS info.

Those are available in the spec, which costs money.
As an alternative, a couple of us have figured out the formats of many of the sentences, and it is implemented in a Perl decoder program at:

<ftp://ftp.eskimo.com/u/a/archer/gps/gps.pl/>

The format of each sentence is easy to figure out from the Perl code. Each sentence has it's own section. The code is free (GPL'ed).

Enjoy,

Wireless application protocol. It is used for internet enabled PCS phones, basically a binary version of simplified HTML. Your phone connects to a wap gateway, which in turn connects to normal web servers. However, the documents are written in either HDML (handheld device markup language) or WML (wireless markup language, derived from HDML and XML), and cannot be viewed in normal web browsers.

There is nothing on my wap server that isn't available on my regular pages, but if you want to see what it looks like and don't have a WAP phone, you can download a development kit from phone.com (they make the

wap gateways) for free which includes a simulator that runs under Windows or Solaris. Make sure you get the HDML 3 version, not the WML version if your goal is to see my pages.

Hello, I'm the author of UIDIGI the APRS digipeater firmware for TNC2.
Actually I'm using as software version number the experimental destination APZxxx.
Now that the code has overcome the experimental phase, is considered stable and is used from several digipeater sysop around the world I want to obtain a reserved APRS Software Version Number for it.

Whoever knows who release these numbers?

Thank you in advance.

People have been asking for the ability to enter positions directly via the web. I have resisted, because of the need to manually maintain user accounts. I have now created an automatic system to do the admin, and a cgi to do the data entry. I'd like to put it out for beta test to the people on this list before I open it up to the general community.

You can read more about it and request an account at:

<http://www.findu.com/account.html>

and more about how to enter positions once an account is active at:

<http://www.findu.com/input.html>

Comments welcome...

Seems to work well - although clicking the top map gives you a very detailed position plot that really means that position ambiguity is a good idea.... even my local village road showed up with the cinks in the right places!

Now - what would be MOST useful IMO would be for the database to be updatable with a simple email. I can send emails from my 9110 wherever I am - much more easily than firing up a web-browser.

Just a thought.

Carl.

aprs.com is a Canadian relocation service. If you mean aprs.net, findu is
a client of APRServe/aprsd, there is no link in the other direction.

Hi All-

I am in the process of formulating a proposed extension to the protocol for mult-point lines- and I cannot resolve something in the present spec. In Chapter 11 (page 60) regarding "Area Objects" the text states

"any size from 60 feet to 100 miles".

the offset is then defined as a two digit number representing the square root of the offset in hundreths of a degree. The smallest offset (besides zero) would therefore be "01"- which my math is:

$01^2 = 1 = .01 \text{ degree} = .68703 \text{ miles}$ if we were talking about longitude at the equator = 3627 ft

Largest offset would be :

$99^2 = 9801 = 98.01 \text{ degrees} = 6732 \text{ miles}$ at the equator

I must be misintepreting the spec.

Sender: bounce-aprsspec-11589@lists.tapr.org
Precedence: bulk

Hi All-

This proposal is an outgrowth of my need for random multipoint line and polygon output of NWS watches and warnings. After my small talk at this years DCC where there was some discussion of this need, I sat down next to Bill Diaz who suggested making the offsets positive and negative and divorcing it from the position of the label- which solved a lot of the problems I was having thinking of a viable spec. So here goes-

(I will be refering to the Chapter 11 page 60 and 61 a lot- this will make more sense if you have a copy handy)

The present spec for area objects has enough room left in it to use the lower case "L" for the symbol. The present spec for the "T" (type) only defines 0 through 9 - leaving everything else available for other types of objects. These could be multipoint lines, polygons, singular points etc. to

be defined later.

The next character would be a "feature" character which would be how to display the object (if possible). This would consist of color, filled area, and flashing etc. and would be dependant on the display software's ability.

Next would come the "Scale" character. This hung me up for 2 weeks trying to come up with a scheme that was versitile and nailed the two scales I need the most- hundreths of a degree and tenths of a degree. The NWS uses hundreths for the "Area of Maximum Concern" output for tornados, severe thunderstoms ect. and tenths for watch boxes issued by the Severe Storms Forecast Center. It would be also useful to be able to generate a small scale map "on the fly" for something like a 10k walk or a bikeathon--- on the other end of the scale it would be nice to plot the ground track of AO-40 while it was at apogee. So the smallest is a ten-thousanth of a degree - around 10 yards or meters. Largest is about 200 miles. This is the smallest offset from the reference point for a given scale factor.

the scale is defined as scale character = (integer (log to base 10 of the scale factor relative to .0001 degree) X 20) + 33

Example: tenths of a degree would be -- scale factor = 1000 or (.0001 X 1000 = .1 degree)

log to base 10 of 1000 is 3

3 X 20 = 60

transmitted character would be 60 + 33 or ascii 93 = "]"

This means that .0001 degree = "!" .001 degree = "5" .01 degree = "I" .1 degree = "]" and 1 degree = "q"

Top of the scale would be "{" which I am loath to transmit since it generally means a message number follows-

so probably limit the scale to "z" = ascii 122 (122-33) = 89 89/20 = 4.45 which is log for 28,183 or a scale factor of 2.81 degrees or about 200 miles

end of part one

(Just noticed I miss-named the first part of this message "Multiline"
instead of "multi-point")

Now that we are all confused- lets procede:

Following the "Type" "Feature" and "Scale" characters comes a string of two
character offset sets

Each set consists of a latitude and a longitude offset character such that

Offset character = (integer (offset in degrees / scale factor)) + 78

Range is limited to 44 scale factors plus and minus from the reference for a
given scale.

Upper case "N" = ascii 78 which would mean zero offset

Lower Case "z" = ascii 122 = +44 scale factors (122 - 78 = 44)

Double Quote " " " = ascii 34 = - 44 scale factors (34 - 78 = - 44)

Since we have a two character scheme for offsets and there are anywhere from
39 to 46 characters left before the string gets too long for the network-
that means the object can have as many as 20 to 23 points (a small map!)
Remember that the points may be ends of lines, corners of polygons, or

simply points - and that they can all be offset from the reference point contained in the preceding part of the packet (either compressed or full position report) This means that the position report can be the label for the set of objects - the label will display on all present software without the multi-point stuff.

Uses for this protocol I can think of:

NWS boxes and odd-polygons

Last 20 lightning strikes

On the fly Maps

Routes

Extremely low resolution radar (!)

I will try to generate some example packets this week-end

73 de kg5qd Dale

I just did the objects in APRSdos and

01 made a rectangle 150' by 200'
02 made it 700 by 950
03 made it .31 miles by .4 miles

I dont have time to check the details, supposed to be raking leaves...

bo

The APRS spec frequently refers to "printable ASCII characters". I presume that it is using the term with its normal meaning of ASCII character codes 32 to 126? If it is, then strict adherence to the spec for the content of beacon comments, messages, object names, etc, would seem to present a problem for users whose native language makes use of accented characters.

An interesting observation. The thing we were trying to avoid was
imbedded TABS and Line feeds and FORM Feeds and other control characters.
I think that most TNC's operate at n,8 1 and so it wouldn't matter. It
would be nice to test against conventional TNC's and quantify the problem
(if any)....

Bob

Roger,

"printable ASCII characters" isn't what causes a problem. ASCII in general is what causes the problems. Being an "American" standard, ASCII was designed to use a small number of bits to represent the English Alphabet. And that doesn't even come close to what is needed to represent the characters of other languages. That's why Unicode was created. 16 bit representations of alphabets from across the world.=20

If you think that using one of the above 128 characters is a solution, then it's only a solution in the narrow realm that the creators of ASCII though in. Dependent on the character set that you are using, the characters can have a wide variety of displays. And if I'm not mistaken, APRS doesn't attempt to use character sets.

So yes, my take is that you are absolutely correct. The option is to implement character sets and Unicode which would double the packet lengths.

Wanna try Kanji?

I'll agree that it was a very self-centered attitude that create ASCII and the same attitude that has continued it's use. But it's also an attitude that has allowed us to reduce by 50% the transmission time and storage requirements.

Ed Woodrick

I've often wondered at the reluctance to use the lower end of the ascii
set, with it's standardized chars for various packet structure elements.
That's what they are there for.

Unicode is a quantum leap from "printable ASCII"! All I was really asking was whether "extended ASCII" - character codes above 127 - should be allowed in APRS messages, etc. After all, it's been done on "normal" (mailbox) packet for many years. Transmission and storage requirements would be exactly the same as now.

My point is that there really is no such standard as "extended ASCII"
What might print as one character for you isn't the same for someone
else. It depends on the character set that you are using.=20

I am having difficulty getting basic position reports with course/speed to work in my application. I have read the (very well done) APRS spec, and I *THINK* I'm implementing the spec. However, my code does not seem to be working.

Here's a packet that I received at my home station:
N7XUC-2>APZPAD,WIDE2-2:/232352z4118.39N/10534.56W>122/000SmartPalm Beta

The "SmartPalm Beta" is supposed to be a comment. However, Xastir and findu both treat the 122/000 as a comment, too. The 122/000 is supposed to be a course of 122 degrees at 000 nm/h.

My question is simple:

Did I do this right? If not, what is wrong?

--

Joel Maslak
N7XUC

P.S. In case you are wondering, I'm implementing a clone to the HamHud on the Palm. A very simple display, like the HamHud. It won't be a replacement for PalmAPRS, as it will not include mapping, nor will it replace the HamHud, as the HamHud is a nicer and cheaper package for a vehicle.

> someone else. It depends on the character set that you are using.

Yes, it isn't perfect. But it works well enough to be widely used on "normal" packet. You only get real problems with Windows software that uses the standard Windows ANSI character set, but that, of course, is a problem for the developer...

k

Looks OK to me. Usually in such cases, I insert a "/" between the end of
the SPEED and the beginning of the comment to make it more readable.

Maybe that "/" got into the spec or into Xaster and FINDU?

bob

Hmm, seems ok to me. A quick pass through the decoder I'm working on seems to be able to decode it too.

```
<?xml version="1.0"?>
<station>
  <callsign>N7XUC-2</callsign>
  <messaging>>false</messaging>
  <position>
    <type>uncompressed</type>
    <latitude>41.3065</latitude>
    <longitude>-105.576</longitude>
    <ambiguity>0</ambiguity>
    <symbolTable>primary</symbolTable>
    <symbolCode id=30>Car</symbolCode>
    <course>122</course>
    <speed>0</speed>
    <timeReported>2000-12-05T21:03:33Z</timeReported>
  </position>
  <comment>SmartPalm Beta</comment>
</station>
```

Lets see what aprsdec thinks:

```
N7XUC-2>APZPAD,WIDE2-2:/232352z4118.39N/10534.56W>122/000SmartPalm Beta
APRS Data Type= Posit w/ time. No APRS
Day= 23 Time= 23 hours 52 mins UTC
Lat= 41 deg 18.39 min N Long= 105 deg 34.56 min W
Icon= Car Overlay= (none)
Course= 122 deg Speed= 000 knots (0.0 mph 0.0 kph 0.0 m/s)
```

Looks good!

From: bounce-aprsspec-14840@lists.tapr.org
[mailto:bounce-aprsspec-14840@lists.tapr.org] On Behalf Of Joel Maslak
Sent: 05 December 2000 16:53
To: APRS Spec Discussion List
Subject: [aprsspec] Position reports w/ speed/course

I am having difficulty getting basic position reports with course/speed to work in my application. I have read the (very well done) APRS spec, and I *THINK* I'm implementing the spec. However, my code does not seem to be working.

Here's a packet that I received at my home station:

N7XUC-2>APZPAD,WIDE2-2:/232352z4118.39N/10534.56W>122/000SmartPalm Beta

The "SmartPalm Beta" is supposed to be a comment. However, Xastir and findu both treat the 122/000 as a comment, too. The 122/000 is supposed to be a course of 122 degrees at 000 nm/h.

My question is simple:

Did I do this right? If not, what is wrong?

--

Joel Maslak
N7XUC

P.S. In case you are wondering, I'm implementing a clone to the HamHud on the Palm. A very simple display, like the HamHud. It won't be a replacement for PalmAPRS, as it will not include mapping, nor will it replace the HamHud, as the HamHud is a nicer and cheaper package for a vehicle.

While Unicode would definitively the way to make the APRS standard
more international, why use the fixed width 16 bit UTF-16 characters.
Use the variable length UTF-8 instead.

In UTF-8 all 7 bit US-ASCII characters are encoded as a single byte.
In fact you can not tell from the byte stream if you have pure
US-ASCII or UTF-8.

All extended Latin, Greek, Cyrillic, Hebrew, Arabic etc. characters
are encoded by two bytes/char.

East Asian characters are encoded by 3 bytes/char and in the future,
dead languages, such as Hieroglyphic will be encoded with 4
bytes/char.

In the US-ASCII range 0 .. 127, the high bit is cleared. In all other
bytes, the high bit is set (in both the lead byte and the follow up
bytes), thus, there is no risk for an extended character byte to be
incorrectly interpreted as CR, TAB, XON, XOFF etc. in any PC to TNC
interfaces or some internet gateways relaying on some strange Telnet
libraries.

However, the 8th bit must be properly handled end to end, but if there
still are equipment that do not support 8 bit characters, they deserve
the same fate as dinosaurs.

What if CW didn't include an "a" or an "e"? Wouldn't that make it really hard to spell a lot of words? Since American English doesn't make up 100% of the languages spoken on this planet, a LOT of people have problems. How would you like to not be able to spell your name in CW or packet? Or maybe not write your city's name? There are many situations where this exists.

A lot of the world is pretty upset with the "Americanizing" that goes on. It was bad enough that we changed the spelling of thousands of family names as they came through Ellis Island, we don't have to continue the practice.

Why should APRS (or any transcribed communications) support International Character Sets? Because the great majority of names and words used around the world can't be represented in US ASCII.

While we Americans might think that we are the focal point of the world, reality is far from it.

How would you like it if Kanji was the only character set supported by APRS?

I'm not saying that APRS should be modified to support non-ASCII. Overall, that would be extremely tough. But then again, any new specifications should at least attempt to start addressing the issues. Non-ASCII is actually pretty tough when you factor in the transport that is used. Email systems, using similar transports, often do a compression to 6 bit characters for transmission of the data. Because there are still some transports that have problems with 8 and even 7 bit characters.

Ed Woodrick

A decade ago there were a lot of problems getting 8 bit characters through some mail gateways, but fortunately there was a lot of security bugs in these systems, so these had to be updated and with the new versions, the 8 bit support sneaked in also :-). So anybody complaining that the 8 bit characters will not get through, also announce that they have a system full of security bugs.

A haven't seen 6 bit character sets since 36 bit mainframes (Univac etc.), but these usually had also a 9 bit character mode. DECsystem20 had five 7 bit characters packed into a single 36 memory word. Apart for these few exceptions, I can not think of architectures that could not handle effectively 8 bit characters.

The reason for 6 bit encoding of _binary_ data is that many gateways are written in C and which the NULL is the string terminator, thus any actual NULLs in the message would be lost.

Returning back to APRS, there are several ways in which non-US-ASCII characters could be used.

There is the old 7 bit ISO-646 standard with dozens of national variants. Some code points in the US-ASCII ([] { } \ | etc.) are replaced with national variants. A code page usually only supports one or two languages, thus, some means would be required to communicate the code page in use when sending a message from one country to an other. This was the method used in computing until the early 1980's. Unless the code page number is contained in the same message, there is going to be a lot of incorrectly displayed text. We would end up with the same mess as back in the 1970's and 1980's. I have written bilingual Finnish/Russian and English/Arabic applications using 7 bit code pages and I do not want to experience the same mess again with frequent code page switching.

If non-Latin 7 bit code pages are in use, you can not display the Latin letters A .. Z at the same time.

However, if 8 bit characters are supported, then some variant of ISO-8859 could be used, each supporting a large number of languages. But then again, the code page number would have to be transmitted in the message going from one language group to an other.

UTF-8 also requires an 8 bit transport, but the advantage is that there is no need to communicate the code page in the message, since each character has a unique code all over the world. For English, the code is as effective as US-ASCII, for languages using some form of the Latin script, the size is about 10 .. 20 % larger than ISO-8859. For scripts like Greek, Cyrillic, Hebrew and Arabic, the size is twice as large compared to the appropriate ISO-8859 variant.

In the Finnish amateur radio CW exam, the characters *f* (di dah di dah) and ÷ (dah dah dah di) are required. Also ≈ (di dah dah di dah) is used in communication but not required in the exam.

Even the ARRL Handbook list quite a few international characters, so it should not be too hard even for Americans to know that other character sets exists. Older Handbooks (e.g. 1991) even listed Japanese, Thai, Korean, Arabic, Hebrew, Russian and Greek Morse codes.

I am writting a small tracker/display application, and came across a few things which made me scratch my head. Simply put, there are some things in the spec which are not implemented by even the most popular APRS programs. There are other things which, while implemented, are implemented slightly different then the spec.

Someone who works in the computer industry will immediately say, "this isn't unusual!" It's not, as there are many, many different TCP/IP implementations, and I know of none that follow the actual TCP/IP spec! However, the spec was written for a reason, and any software designer should try to follow it whenever possible.

Here's a short list of inconsistancies I've found:

- 1) Some packets end with a CR. This is part of the actual packet, not a fault of my system! This is due to the SENDPAC character being a LF - when programs send a CRLF instead of just a LF, the CR becomes part of the packet. The spec indicates that the trailing CR should NOT exist.
- 2) Other programs send BOTH a CR and LF! This is most common in "dumb" trackers. Chances are, it is a bug in the TNC firmware. Once again, this is outside the spec.
- 3) The Course/Speed extension simply does not work in most software. I've actually tested WinAPRS, Findu, and Xastir, although I'm sure it doesn't work in most others, either. This extension is treated like part of the comment by these systems. Thus, the longer \$GPRMC string needs to be sent if this information is important to you.
- 4) Compressed packets are not understood by many simple applications. This causes our bandwidth usage to increase.

Let me recommend, as always, that any software is liberal in what it accepts and conservative in what it sends. If your software does one of the above, you would be doing the APRS community a service by fixing it! However, any author should expect the above things to occur. A simple reading of the spec will not alert you to these possibilities.

Are we doing ourselves any good by accepting packets that don't conform to spec?

I think it mainly prolongs the agony.

I used to work on software that moved money around. (Credit card payments)
We used an approach that could be summarized as "take the first opportunity to throw the packet away, and if it survives all tests, then act on it".

We had almost zero instances of crashes caused by bad packets.
The one time we had a problem, it turned out to be a bug on our end, aggravated by an LRC routine that worked from back to front, when all the other parsing ran from front to back, and a bug in one of Visa's five Tandems, that output the first 10 bytes of the packet twice, if you nacked the first (correctly built) packet that it sent, possibly due to line noise. It took 7000 transactions to isolate the exact sequence of events. This was done using simulation software written especially for this job.

The bad packet looked like this:

```
<STX>first 9 bytes of data repeated<STX>real data<ETX><LRC>
```

The LRC routine started at the back, rather than the front, and stopped when it encountered an STX, so it passed the packet.

Then the parser then took what should have been the numeric date, (based on the position relative to the first STX), and ended up putting alpha information into a numeric only field, with disastrous results.

Had our LRC routine been written properly, we would have NAKed this packet (bad LRC), and the bug in the Visa host would have been found and fixed MUCH earlier.

Granted it's not APRS, but there's lessons to be learned here.

If "reject the wrong or questionable" was the way that your email client worked, then you probably would never get any email. As to Internet Standards, the motto is usually "accept anything"

The "accept anything" goes a lot further at allowing specifications to be expanded over time.

What is needed in situations like this is testing suites that can validate that a program is acting properly.

True, but the email client has a human to back it up. It's not going to go
do things automatically based on the content (unless it's outlook express,
automatically installing and running viruses :)

If the data is going to be acted on automatically, then we need to be sure
that it's actually valid.

>The "accept anything" goes a lot further at allowing specifications to

You can always define "optional data" fields, and byte flags with openings
for future definition.

>What is needed in situations like this is testing suites that can
>validate that a program is acting properly.

We must have a PC programmer or two on this list who could write something like that.

When I was into this game, we had a language called "mimic", and I would write a routine that would send every possible valid packet, with several different sets of example data. In the example I gave, I wrote a terminal simulator that ran the transaction over and over, and simulated every sort of error I could think of, on a random basis. It trapped the host responses, and when the host said something illegal, I had the exact data that caused that output. Set it up, and let it rip.

In an APRS version, on the client end, you would see stations appear, move, send messages, weather, whatever else is doable. The tester would examine and interpret your output, and log anything it couldn't understand.

I would also send bad/malformed packets, both on a randomized basis (simulating noise hits) and specific bad packets that had triggered bugs previously (makes regression testing much simpler)

If I were a PC programmer, or still had access to Mimic, I'd volunteer to write this.

David,

There's a lot of applications that automatically process Email messages.
A lot.

But even without end-stations processing messages, all of the
intermediary stations "automatically" process the messages.

Oh, let see if I can think of another "automatic" processor? Maybe this
list itself?

And "optional fields" only work to a certain degree.

Ed

True, but the email client has a human to back it up. It's not going to
go

do things automatically based on the content (unless it's outlook
express,

automatically installing and running viruses :)

If the data is going to be acted on automatically, then we need to be sure that it's actually valid.

I have a couple more APRS spec/implementation issues.

First: Neither WinAPRS, Xastir, or the HamHud seem to understand a rejection message. This contributes to excess QRM, as the rejection message gets ack'ed, and the original message will continue to be resent forever (or until the user kills it). So, it is better right now to ack ALL received messages - even in stand alone trackers - and then send a normal message stating that the site doesn't have an operator.

Second: We might want to rephrase the Multiple Acknowledgement section on page 72. It tells us that we should separate acknowledgements by 30 seconds and also transmit multiple acks on a long path -- both of which make a lot of sense. However, the first sentence is misleading:

"If a station receives a particular message more than once, it will respond with an acknowledgement for each instance of the message"... I have a home station within range of two wide's. If someone uses a path of WIDE, while they are also in range of my home station, it will send *THREE* acknowledgements. What makes it even worse is that the acknowledgements are sent out via the default path - WIDE3-3! Thus, I end up getting at least 4 acknowledgements, assuming the dupe checking on the digis works like it should (in reality, I get about 6). This is a fairly significant amount of QRM, if you ask me. The worst part is that this QRM goes through 200 miles of network - multiple times! The solution I propose (and implemented) is to SURPRESS duplicate acknowledgements for a period of 30 seconds after a message is acknowledged.

I guess this proves that we need an APRS test system. Unless someone else sends me an e-mail that they have already written one, I'll start writing one in Perl for the Linux OS. I foresee it having a scripted "standard" set of APRS tests and two modules: a generic APRS module and a TNC-specific module (I'll be implementing the TNC for the Alinco 135, since that is what I use in my car). It will connect via a serial port to an APRS application (yes, you will probably need two computers or a null-modem cable - however, it is hoped that at least the big radio companies might be able to secure the needed equipment for the test). However, don't expect me to have anything like this finished before two or three months from now!

I previously suggested implementing sequence numbers in the packets. Each packet from me has a sequence number, if you get the same sequence number, and the same callsign, then you know it's a dupe which does not need to be acked, without examining anything else.

Presumably you have space to keep a short list of recent packets, or just the source callsign and sequence numbers.

We ran into this problem in credit verification, when the terminals got the ability to send multiple transactions per session. If the host acks my first packet (an approve/decline response is interpreted as an ack), but the link trashes the ack to a nak (either explicit nak, or a trashed response packet), then I send the same packet again.. The host would get two packets, and think that they were two separate transactions, resulting in multiple charges. Sequence numbers solved that entirely.

You may still need multiple acks to make sure that one gets through, but at least you don't end up multiply acking all the dupes as well.

For the benefit of those of us who are not members of the Working Group,
I wonder if someone could post a list of the current members and say
with what software product each of them is involved?

Also, I think it would help if others who post suggestions for changes
to the spec, changes to the behaviour of existing software, etc, could
also identify whether they are speaking as an active author of an APRS
program, a would-be author, or just expressing an opinion as an APRS
user.

(See my sig for my involvement with ham radio software.)

First, keep in mind the spec has been official for only a couple months.
Second, since version 1 of the spec is supposed to describe what is
implemented, any mainstream APRS application that deviates from the spec
may well reflect an error in the spec rather than the program.

>Here's a short list of inconsistancies I've found:

I just looked, and I could not find where the spec states the data can't
end in cr,lf,crlf, or any other combination, can you point it out to me?
In any case, it is certainly likey that errors like this will continue,
and your program needs to be robust enough to handle it. Both of these
problems exist within the tnc where no one on this list can do anything
about it.

- > 3) The Course/Speed extension simply does not work in most

> sent if this information is important to you.

Well, it works on findu, sometimes. On my recent trip I checked in frequently via WAP, and found about 25% of my posits had a course and speed. This is a bug I've known about for a while, and had looked briefly at the code to figure it out, but couldn't, so it got placed on the do list, where it presently resides at 87 of 139. Don't hold your breath! I've made it as clear as I can that findu is in a very early state of development, but it is not fully APRS compliant, never has claimed to be, and likely never will be. In all the time it has been up, no one every emailed me that there was a problem, and as long as that is the case, it will get buried deeped and deeper on the list...

It just came to light that the spec says it is OK to not have a trailing / after the course and speed, but since all the mainstream programs use one, it may be the source of the problems you note. Agains, since the spec is supposed to represent what exists, the correct action might be to add it to the spec, but that is up to the APRS WG, not you or I. You might want to repeat your test adding the slash and see what your results are.

> 4) Compressed packets are not understood by many simple
> applications. This causes our bandwidth usage to increase.
>
base 91 compression is 125 of 139 on the findu do list...

Steve

I'm brainstorming on another project and could use some insights from any who feel that they'd like to provide input...

In the APRS world, what are the various types of network functions (RF Only at this point, please) that are present?

Function	Invoked by these aliases
Digipeating	WIDE,RELAY,TRACE,WIDEn-N,TRACEn-N,mycall
Gateway	GATE, IGATE

Any others come to mind?

Ev, W2EV

If the E105 is the same as the E115 (and the look the same :)) then the PC comms link automatically grabs the com port when you plug something in. On mine I have to click

programs|settings|connections|pc| and then uncheck the 'automatically synchronise' box.

Its a PITA achully :)

APRS/CE is nice tho - and the latest beta version handles all DosAPRS maps very well.

There is a list group for APRS/CE and all other ham related use of the pocketPc on www.egroups.com called hampocket - has about 25-30 members when I last looked so its not high-bandwidth :)

send an email to hampocket-subscribe@egroups.com

I think will subscribe you, or else you can to surf there.

I have yet to get mine to work with a v5 ROM TINY-2, but it is very happy with the kenwood THD7E

Apparently UI-View has implemented its own messaging format that is not compatible with the APRSSpec. Since it uses the TOCALL as the actual message TO-CALL, the APRS front end filters for ALTNETS will ignore these messages. I have no problem with this, its Roger's program... but it does raise the question of whether we want to add this to the APRSSpec as another form of messaging? Or whether we all want to add reception of this to our code...

It looks like he puts a tilde (~) as the first byte of the data (message) field and ends with ~xx which appears to be a line number for acking... I havent seen any acks to know... (of course this will cause stream switching and confusion to a dual Port KAM on HF with the use of the reserved "`" stream switch character...)

My only concern is that since UI view is predominately used in Europe and this messaging is not compatible with other APRS versions... it could lead to a divergence in the long term that will cause confusion to users who both think they are running "APRS" but in fact are not able to communicate.

Maybe when a UI user uses this form of messaging it is very clear that this is not APRS compatible, and thus there is no reason to be concerned since the user has made a conscious choice to not use APRS format... sort of a semi-private form of messaging...

I'm not taking any position here, it is just something I learned about today, and thought we might want to be discussing the implications of new formats on existing APRS networks...

Just a thought...

Bob,

Perhaps this was a decision by Roger to make UI-View
messaging non-compliant with APRS?

If changes were made to the spec to accomodate this

deviation, it would be a long time before existing APRS applications could correctly handle this. Some may never be changed.

Is the APRS WG still active? Haven't heard anything lately. Wasn't one of the tasks of this group was to check to see if applications were APRS spec compliant?

I don't think Roger was ever invited to participate in any case.

If individual authors can unilaterally add non-compliant messaging then the specification is not serving its purpose.

Bill KC9XG

In article <LYR13460-128458-2001.01.06-15.30.19--roger#peaksys.co.uk@lists.tappr.org>, Bob Bruninga <bruninga@usna.edu> writes
>Apparently UI-View has implemented its own messaging format that is not
>compatible with the APRSspec.
Etc...

Just a little "scene setting" - When I started writing UI-View well over two years ago, and developed its message format, compatibility with a non-existent spec for a protocol that was covered by a copyright claim, was not something that ever crossed my mind...

However, UI-View now supports both its own and APRS format messages, and I have given a great deal of thought to doing it in a way that should not cause a problem for users of other applications:-

If you install UI-View on a PC in the USA or Canada, then, provided the international settings in Windows are correct, by default the user does not have the UI-View message format option available. In other parts of the world, both message formats are available, and the user can set the default type.

If UI-View receives an APRS format message, then any future messages sent to the originator will default to being in APRS format.

UI-View will not pass UI-View format messages to an internet server, because my philosophy is that only APRS compatible traffic should be passed to the servers.

>I'm not taking any position here, it is just something I learned about
>today, and thought we might want to be discussing the implications of new
>formats on existing APRS networks...

As you will see from the above comments, it's not a "new format". Also, in most of the countries in which it is used, the level of APRS activity was virtually zero before UI-View became popular - there were no "existing APRS networks". I don't think any European countries even had

an APRS frequency allocation.

In the new era of "open" APRS, I've thought about removing the UI-View message format, but I don't think it causes any problems, and it does possess some advantages compared to APRS format messages. E.g. shorter frames, and parallel transmission, with reordering of messages received out of sequence.

Good, thanks. Thats good that it automatically knows to send APRS to APRS stations... and the user is clearly aware that he is using a different format so that other APRS stations wont see their messages...

> As for the stream switch char that does not have to be a problem, just use
> kiss mode, it is recomended anyhow as it gives the program more control

GOod point. It only affects the sender, and since it is Uiview using KISS mode, then again, there is no problem with the tilde...

Thanks..bob

UI-View has done this for since before it was APRS compatible. UI-View was designed before APRS hit the UK but since it did Roger has included support for an increasing number of APRS elements.

--- From the help:

UI-View(32) supports two formats of message - it's own format and also APRS format. Although UI-View(32) format has some advantages over APRS format, users of other APRS software will not be able to receive UI-View(32) format messages. If you operate in an environment where most users aren't using UI-View(32), then you should use APRS format.

(and also...)

The default value for "No UI-View(32) extensions" varies depending on what country you are in. When UI-View32 is run for the first time, it checks your Windows country code against the list in the file NOEXTN.COD. If your country code is in that file, then UI-View32 extensions are disabled. Note that this only happens the very first time UI-View32 is run, so if you alter the setting for this parameter, UI-View32 won't change it.

--- End

An on-topic discussion would be if UI-View format could help improve APRS format in the future?

Yes, I am always open to exploring new ideas. For example, some of us have implemented a "free-return" ACK protocol, that embeds a reply ack in all outgoing messages to help improve a two-station dialog.

This was done completely within the bounds of the protocol and the technique was shared with all the authors. It really speeds up dialgos since the ACKS are being now "forced" from the receiving end but with a free ride.. Its just an example of learning new ways to do things without tearing apart the spec...

They're not exactly blank, if message lines are missed, they are
replaced on the screen with lines saying e.g. -

seq. number 01
seq. number 02

Where the sequence number represents, in APRS terminology, the message
identifier. If/when those lines are received, then the "seq. number"
lines are replaced with the message lines.

This system can only work if the message identifier has a known, logical
format. So it would never work with APRS messages, because the message
identifier can be any random collection of "up to 5 alphanumeric
characters, no spaces".

Thanks Roger,

And it looks like you made ver good provisions to assure there were not
incompatibilities of use... G0od work...

Actually, I liked the idea of parallel messaging also as just another
tool. Selectible when useful, or sequential at other times when
important. I was going to add it to APRSdos but then Sprouls then
abandoned it in WInAPRS because they did not have a means for assuring
that missed information was obvious. I like your "blank" line approach...

Yep, that is the problem of a spec by committee. I always wanted and used
-sequential- numbering. They could be any numbers, but within one
message, I wanted them sequential for just the reasons you mention. But
other authors did not want to be bound by anything...

I do think that all of them do do things sequentially, but we can't prove
that now. oh well...

People

One thing missing from the APRS spec is a brief summary of the common NMEA strings used by hams. There are only three or so, and these should be implemented in most software...

More importantly it seems that by using my D700 Kenwood in TNC mode I can transmit positions using an undocumented format, which might appear on air. The format is

```
VK2TDS>GPS:$PNTS,1,0,10,01,2001,001853,3400.4672,S,15051.7165,E,34,54.00,0,,  
000,1*2E
```

Most of it is easy to work out, but I think the speed and direction is somewhere encoded after the position...

This string is also the default (!!??) string that the Alinco 135 will transmit.

The Alinco 135 TNC docs are very helpful with regards to the NMEA strings. I have these in electronic form, and I would be glad to send them to anyone who asks off-list. Please let me know if you want the .txt version (kind of hard to read) or the .pdf version. Note that I could not locate ANY copyright string, so I'm assuming that this material is public domain. If someone from Alinco contacts me and informs me otherwise, I will stop distributing it (although if you read the docs, you will like most of what you see).

As obligatory note for the SIG:

The \$PNTS string is defined as:
(straight from manual)

5-4-7 \$PNTS This is a private-sentence based on NMEA-0183. The data contains date, time, latitude, longitude, moving speed, direction, altitude plus a short message, group codes, and icon numbers. The EJ-41U does not analyze this format but can re-structure it.

The data contains the following information:

- * \$PNTS Starts the \$PNTS sentence
- * version
- * the registered information. [0]=normal geographical location data. This is the only data EJ-41U can re-structure. [s]=Initial position for the course setting [E]=ending position for the course setting [1]=the course data between initial and ending [P]=the check point registration [A]=check data when the automatic position transmission is set OFF [R]=check data when the course data or check point data is received.
- * Dd/mm/yyyy/hh/mm/ss: Date and time indication.
- * Latitude in DMD followed by N or S
- * Longitude in DMD followed by E or W
- * Direction: Shown with the number 360 degrees divided by 64. 00 stands for true north, 16 for east.
- * Speed in Km/h

- * One of 15 characters [0] to [9], [A] to [E]. NTSMRK command determines this character when EJ-41U is used.
- * A short message up to 20 bites. Use NTSMMSG command to determine this message.
- * A group code: 3 letters with a combination of [0] to [9], [A] to [Z]. Use NTSGRP command to determine.
- * Status: [1] for usable information, [0] for non-usable information.
- * *hh<CR><LF> the check-sum and end of PNTS sentence.

** This is not a note that is intended to startup a debate over
privacy **

===== Introduction =====

With the advent of the January VHF Sweepstakes this upcoming

weekend, there will be several Rover-class stations activating their stations with UI-Packet on-board. The purpose of which is to announce their location (as a TX-only tracker) using all-amateur means.

They will be *not* using 144.39 MHz (the reasons are many, all of which have to do with assuring VHF Sweepstakes rules compliance).

I know that at least one APRS software title understands the RFONLY alias as a request from the sending station to *not* translate the posit to any other port (effectively keeping the posit from being passed to the Internet [a non-Amateur means of communication]). As a result, non-roving stations are being trained on the use of UI-View (thank-you, Roger!).

==== All of that for this simple question ==== :o)
Is there any other "APRS" software title that supports the RFONLY alias? If so, I'll also promote their use.

Ev, W2EV

I was not aware of this alias. So I doubt any of the APRS authors have
included it. (or I was asleep when it was discussed)... To my knowlege
all that discussion and blood we had about the issue resulted in only
filters on FINDU... no one (except apparently Roger) implemented any
RFOONLY type filtering? Of course it wont help with hardware-only
TNC-TCPIP Igate feeds, but there are not many of them...

But the simplest way to insure something is RF only is to use 3rd party
format. ALL Igates to my knowledge will "assume" that a 3rd party packet
was an IGated packet and so will not re-inject it into APRServe...

APRSDos supports this under the command alt-SETUP-FORMATS-3rdparty

Or at least the above is what I remember...

bob

Ev,
 AFilter supports NOGATE.
IGATES using AFilter can reject packets that contain NOGATE in the header.

I implemented NOGATE and RFONLY by default, other "no gate" aliases can be configured.

I put it in with a proviso that it wasn't a lot of use unless other forms of IGATE used something similar. (Here in the UK it is some use, because most of the IGATEs are running UI-View.)

Referring to the RFONLY alias, Bob Bruninga wrote:

> I was not aware of this alias. So I doubt any of the APRS
> authors have included it.

RFONLY has been adopted as a BEACONet alias, and is part of the growing BEACONet protocol specification (along with HOPn-N, and the APRS-defunct [GG##gg] position designator). Since the common thread that binds APRS(tm) and BEACONet(tm) is UI-Frame packet, and software exists to decode APRS(tm)-spec frames, it is easy for APRS authors to write-in BEACONet(tm) specific protocol support.

I simply wanted to find out which authors have written-in a specific feature that is important to Rover-category BEACONet(tm) stations. With the hopes that most of the authors (and those that are developing software on the sidelines) would be subscribed to this list...I floated the question here. It was one of those "thinking outside of the APRS(tm) box" questions. That's all, nothing more.

Ev, W2EV

Hi folks,

APRS client applications consider the APRS Internet System's content to be real-time. This restricts the contribution Sunsats and other "APRS harvesters" (and indeed a future ASTARS constellation) can make towards increasing the accessibility of the APRS network. I guess we should start sharing ideas on how this restriction can be overcome.

It is proposed that a header, opened by the < character and closed by the > character, be prepended to all delayed frames fed into the APRS Internet System:

```
<dd_t20010116T151934Z_p7823.92S01161.48W_a685477_f145900k_mAFSK_b1200_vPCSAT,SUNSAT-3,ZS1SUN-15_s1463_cVHF omni test>ZR1CBC-3>APRS,APRSAT:13355.66S/01851.97Eb
```

A two byte alpha-numeric frame identifier, that follows immediately after the opening < character, allows for future extension. The dd identifier, as shown in the above example, indicates that the frame contains delayed data. [1]

Every field starts with an _ delimiter and an alpha-numeric field

identifier, to facilitate parsing. More fields can be added as needs arise. Field ordering is not important. The following fields are proposed, at this stage: [2]

- _t Date and time the frame was harvested (always in UTC), presented in the the ISO 8601 Basic Format.
- _p Position of the harvester, specified by its latitude, followed by its longitude, in the standard APRS formats.
- _a Altitude, in meters, as given by the distance from the center of the earth or above some other standard reference point (still to be determined).
- _f Frequency, in hertz, on which the frame was harvested. An exact format must be determined. Use of the k, M and G unit prefixes (as shown in the example) is preferred.
- _m Modulation scheme used for the harvested frame. An exact format must be determined.
- _b Bitrate, in bit/s, at which the frame was harvested. An exact format must be determined. Use of unit prefixes is preferred.
- _v Path via which the frame enters the Internet. The first callsign identifies the harvester. Comma separated callsigns are appended as the frame progresses. The last callsign identifies the igate.
- _c Text comment for use by the harvester. A length limit should be determined.
- _s Sequence number, assigned by harvester. Incremented by one for every frame harvested.

As soon as a standard is agreed upon and aprsd passes on such frames, we will start injecting Sunsats digilogs (around 600 frames per day, at this stage) into the APRS Internet System.

73 de ZR1CBC, Johann

[1] A similar header, with a different frame identifier, can be used for future acknowledged ASTARS messaging.

[2] Only the _t and _v fields are required; the others are optional.

(I've moved here rather than carry on the discussion in HTAPRS, so anyone who hasn't read the "Problems w/New IGATE Service" thread in HTAPRS might find it worthwhile to do so.)

Seeing as I appear to be out of step with most other authors, I guess I'm going to have to change UI-View to ignore the sending callsign when processing an ack. However, I think the spec is ambiguous in this area, and I would suggest the following changes:-

1. It should be stated that the addressee field of a message need not be a valid AX25 address. I know it doesn't say it should be, but, in the context of packet radio, it's easy to associate a nine character address with a valid AX25 address, and I would presume that is what was originally intended.
2. It should be stated that the combination of originating callsign and message identifier should be sufficient to uniquely identify a message without reference to the addressee field.

APRS was designed to work with data obtained or originated by a TNC that uses the AX25 protocol. If a packet does not conform generally to the AX25 protocol, APRS applications should not be required to relay or display these packets.

I feel that Origination, destination, vias, and addressee fields of messages should be valid AX25 addresses. This simplifies the processing of packets and permits legacy applications to operate without change.

I sympathise with your opinion, but the problem is that, as the spec stands, it is ambiguous as to exactly how both the addressee field and message numbers should be used. My suggested changes would bring the spec into line with what other authors already appear to be doing (based on the discussion in HTAPRS).

> And aren't source callsigns supposed to be AX25 compliant?

Correctly written software (OSI Level 5, 6 and 7) must (by convention) abide by the rules as set forth by lower level protocols. Failure to do so often causes an application to be a "poor neighbor" to other connected systems (see the thread on "Unhandled Exception Errors" for probable symptoms of what some systems may do when encountering protocol-skirting

"aprsdCLE" appears in the source-address field of the frame cited above. It appears to contradict the following AX.25 protocol statements:

===== 2.2.13 Address-Field Encoding =====

The address field of all frames shall be encoded with both the destination and source amateur call signs for the frame. Except for the Secondary Station Identifier (SSID), the address field should be made up of upper-case alpha and numeric ASCII characters only. If level 2 amateur "repeaters" are to be used, their call signs shall also be in the address field.

=====2.2.13.1 Figure 1=====

... The source address subfield is then sent in octets A8 through A14.

=====

"aprsdCLE" uses lower case letters and is longer than 6 "ASCII" octets

(where the callsign goes) and uses a non-numeric value for octet 7 (where the SSID goes). [interestingly, I've found no mention that SSID must be numeric...only that it is something other than uppercase Alpha and numeric...maybe someone can clarify by citing the appropriate AX.25 convention?]

Unless I'm missing something, it seems that this ought to be brought to the attention of the author of aprsd for correction. Of course, I'm neither an author, nor considered an insider. My opinion and \$0.99 will get you a BigGulp at the corner mini market. :o)

Ev, W2EV

In article <LYR1643-130734-2001.01.22-14.18.56--roger#peaksys.co.uk@lists.tapr.org>, Bob Nielsen <nielsen@oz.net> writes
>Of course there are many other areas where the AX.25 specification is
>not rigorously adhered to. For example, the specifications also says
>that destination and repeater addresses, in addition to the source

>address are to be amateur callsigns plus SSID, which excludes such
>addresses as TRACE, WIDE, TCPIP, etc. I don't know if the APRS
>specification addresses this, but that might be an appropriate place to
>address this concern. Of course Net/Rom node addresses do not fit this
>model either. In fact, aliases are not mentioned at all in the AX.25
>specification.

The AX25 spec says that the address field consists of six characters,
plus SSID, and the characters should be upper-case alpha or numeric. The
address I highlighted wasn't an amateur radio callsign, but that's not a
problem - non-callsign aliases can still be legal AX25 addresses. The
problem was that it was eight characters, and some were lower case.

To pick up on PE1RDW's comment in another reply - I would think that the
structure of source addresses should be consistent, irrespective of
whether they originate on RF or on the internet. I can't find anything
in the spec that says otherwise, after all, frames created on the
internet masquerade as AX25 frames.

Not true! My internet-only callsign, LARAMIE, is being gated back into RF
by another IGate who gates all traffic he doesn't hear that is a certain
range from him.

So...weird callsigns COULD crash machines...

Please corect me if I'm mistaken but all the internet trafic gated to rf
is supposed to be as a 3th party frame that would leave LARAMIE as ascii.
If any igate software does it any other way that software is to blame not
the originator.

This is correct and it is what the other igate is doing - properly.

However, my concern is what happens when a station tries to plot my location on a map, assuming that the software plots the third party position reports. If the author assumed that this followed the AX25 spec, he will find that he allocated insufficient space for this call. The result will be overwritten memory, possibly causing a crash. My bet is that a short one like LARAMIE won't overwrite much, and won't be noticed by most people. But, I bet if someone stuck something "THISISAVEERYLONGINTERNETCALLANDIDONT CARE" as thier Internet call, it would crash many bad implementations.

I watched the Wyoming/Colorado network go to nearly 100% utilization in response to a single packet - an IGATE query. You see, the query got gated to the Internet and the responses got gated back to RF. I shut down my igate as soon as I noticed this, as I would rather not provide this service than trash the local RF LAN. Until I can patch aprsd, I'll stay down, too, as I believe that is the only thing I can do that is in compliance with the spirit of APRS. But, read on, for this isn't only an IGATE query problem.

If you send an IGATE query when you are near an igate, thousands of igates will flood your 1200 BPS RF LAN in response to your query, because not only will the local igates respond, but also most igates on the web will too!

Is there even a good reason to have an igate respond to an IGATE query that was sent over the Internet? I understand that it might not be a bad thing for it to respond if it gets the query over RF, as it helps network planners see what is going on. But, does anyone really want hundreds of

machines sending a reply?

Unfortunately, this isn't limited to IGATES. It also affects any other type of query for which thousands of machines could respond... Of course the IGATE is most effective because most of the other things you query for aren't directly connected to the internet.

Solutions?

LONG TERM:

- 1) Packets on the Internet that come from the RF stream should be marked as coming from the RF stream. This way, remote sites can determine if it should respond to a query received on the internet (it is okay to flood the internet; it is not okay to flood the RF stream)
- 2) Igates should have a timeout feature, just like our repeaters do. This prevents an unattended igate from really messing with the RF LAN. It should function on a duty cycle basis - say one packet every 15 seconds or something, possibly taking into account paths and such. IANAL, but I have to think that the spirit of Part 97 requires those of us running unattended stations to make sure that our systems don't interfere with the functions of a communications network.
- 3) The internet servers should automatically filter out broadcast queries that didn't come from the authorized user's call sign. This will prevent gated queries from being responded to by older software.

SHORT TERM:

- 1) ALL IGATES SHOULD BLOCK ALL BROADCAST QUERIES. There should be no exceptions. I'll be writing a patch sometime this week for aprsd. I'll be submitting it to the author and also posting it on the web with a URL for anyone interested in setting up more friendly igate. aprsd isn't the only software at fault, though, so I encourage APRS software authors to look at their software, too.
- 2) DON'T USE AN IGATE (or any other query which more than 1 machine will respond to) QUERY ON RF UNTIL YOU KNOW YOUR LOCAL RF LAN HAS ADDRESSED THIS PROBLEM. This is unfortunate, I realize, but I believe this is the only thing that can be done to keep the network sane.

A week or more ago, a station up in Canada sent repeated IGATE queries one
right after another. Sure stressed the Internet feed.

It is not okay to flood the Internet IMO. Several Servers have maxed out T1 lines, and have had to either limit service or find another site with higher bandwidth. Many of the APRS servers are hosted free of charge by kind souls. We should not abuse this kindness.

Conservation of bandwidth should be practiced on both the Internet and RF. Elimination of excessive ?IGATE? queries is a start.

SNIP

The servers should also filter out packets that are not APRS compliant. Many non-compliant packets are gated to RF, along with packets that contain no payload, defective headers, and assorted garbage packets.

Bill KC9XG

I found this URL while researching the "Degree Confluence Project".

http://www.colorado.edu/geography/gcraft/notes/datum/datum_f.html

Near the bottom there is information on how to translate between different map datums.

Could this info be incorporated into APRS programs to alleviate issues with different MAP Datums We could modify the file format for map files to include information about the datum it uses, then have the program translate the GPS datum (usually WGS84) to the datum used by the map ?

The on-air Datum of APRS is WGS84. APRS+SA has coordinate conversion capability to take coordinate input in any of 100+ different map datums and convert to or from WGS84. It also can convert from Lat/Long to UTM coordinates.

Yes! Xastir uses some limited datum translation capability of the PROJ.4 library (libproj) to do this in order to display USGS topo maps with the correct datum. In my county there's a 90 to 102 meter shift between NAD27 and WGS84 depending on where you are in the county.

If someone wants some GPL'ed example code in Perl that can translate between 231 map datums, get the Coordinate.pm Perl module from my site. It's easily translated to C. <ftp://ftp.eskimo.com/u/a/archer>

BTW: The DOS/Windows maps as used in Xastir are off by what appears to be a datum shift. It looks like the original data was NOT in WGS84 and the program that made the vector maps didn't do a datum shift. It's a Mac program that makes them, right? Closed source?

(This message is posted on the APRS SPEC SIG on a monthly basis.)

PURPOSE

The purpose of the APRS SPEC SIG is to provide a forum for folks interested in discussing the APRS protocol specification.

POSTING MESSAGES

To post messages to the APRS SPEC SIG, send email to aprsspec@lists.tapr.org

APRS SPEC SIG RULES

The APRS SPEC SIG has a few simple rules:

- . Be courteous. Abusive, insulting, or rude behavior demonstrated towards another list member is a violation of this rule.
- . Stick to the subject, i.e., the APRS protocol specification. Subjects that are only tangentially related to the APRS protocol specification (like "what kind of printer should I buy to print out my copy of the APRS specification?") may be considered off-topic. If you start a message with "this is off-topic..." then you are violating this rule.

- . Be succinct when composing a message. (The APRS SPEC SIG software has been optioned to limit the length of each message.)
- . When quoting a previous message, only quote the parts of that message you are referencing. (The APRS SPEC SIG software has been optioned to limit the length of a quote.)
- . Do not send messages in HTML or Rich Text format.
- . Do not send attachments.
- . Cross-posting is not permitted. (The APRS SPEC SIG software has been optioned to prevent cross-posting.)
- . The APRS SPEC SIG administrator reserves the right to suspend or ban any list member who violates these rules.

UNSUBSCRIBING

To unsubscribe from the APRS SPEC SIG, follow the directions you will find at the bottom of each message you receive from the APRS SPEC.

QUESTIONS, COMMENTS, ETC.

If you have any questions, comments, etc. concerning the APRS SPEC, please email the APRS SPEC SIG administrator at the address below.

Hi folks,
APRSHelp is just the ticket. The name is easy to remember, and engenders the right emotion for visiting it. Unfortunately, information is only as good as the source. It does a good job of hitting the "intro" APRS software but contains not much on some of the other Amateur-grown stuff that exists such as Xastir, Afilter, AfilterX, PearlAPRS, UI-View, XAPRS, HamHUD and TinyTrak. (ie- what *is* Afilter and how is it used?)

If you are an author of one or more of these products, would you please forward the web page author some information about your product, so that it may be included there, too?

No, I'm not the author...but you may hit the website to find them. (or <mailto:kc5jgv@arrl.net>).

The potential for this website is great. Please support it with useful information.

Ev Tupis, W2EV

The primary purpose of the APRServe WG should be to improve the integrity of APRS data provided to TCP/IP users. We should begin to discuss some the areas that may require attention.

1. The linking of servers should provide a secure and reliable method of ensuring that all servers obtain all APRS data in a timely manner. The current APRServe network links must be documented. Steve Dimse has indicated that much of this is available. It should be compiled into a single document that can be used as a basis for producing the current network specification. Graphical representation of the network topology should be included. This can then be used to propose future enhancements to the existing network.
2. The present APRS network bandwidth requirements should be analyzed. Many of the sites and connectivity are provided to APRS at no cost. We should attempt to limit the impact that our activities have at these sites.
3. The APRS bandwidth requirements and effects on local RF links should be analyzed. Local RF issues are local issues. The APRServe network should provide a highly reliable feed to IGATES and accept data from verified users. Existing verification procedures should be examined, documented, and new methods proposed.
4. The proposed specification should incorporate provisions to permit the exclusion of data that is not APRS compliant. These provisions, if implemented by a server would eliminate any packets that are not recognized as APRS compliant packets. Servers would have the option of performing limited cleanup of APRS packet headers to remove non-essential TNC display formatting, rather than rejecting the packet outright. Further provisions could be adopted to eliminate APRS packet that carry no information.

No conversion or changes to payload data would be performed on the APRS packet payload information. Mic-E packets would not be converted.

(This message is posted on the APRS SPEC SIG on a monthly basis.)

PURPOSE

The purpose of the APRS SPEC SIG is to provide a forum for folks interested in discussing the APRS protocol specification.

POSTING MESSAGES

To post messages to the APRS SPEC SIG, send email to aprsspec@lists.tapir.org

APRS SPEC SIG RULES

The APRS SPEC SIG has a few simple rules:

- . Be courteous. Abusive, insulting, or rude behavior demonstrated towards another list member is a violation of this rule.
- . Stick to the subject, i.e., the APRS protocol specification. Subjects that are only tangentially related to the APRS protocol specification (like ≥what kind of printer should I buy to print out my copy of the APRS specification?≤) may be considered off-topic. If you start a message with ≥this is off-topic≤ then you are violating this rule.
- . Be succinct when composing a message. (The APRS SPEC SIG software has been optioned to limit the length of each message.)
- . When quoting a previous message, only quote the parts of that message you are referencing. (The APRS SPEC SIG software has been optioned to limit the length of a quote.)
- . Do not send messages in HTML or Rich Text format.
- . Do not send attachments.
- . Cross-posting is not permitted. (The APRS SPEC SIG software has been optioned to prevent cross-posting.)
- . The APRS SPEC SIG administrator reserves the right to suspend or ban any list member who violates these rules.

UNSUBSCRIBING

To unsubscribe from the APRS SPEC SIG, follow the directions you will find at the bottom of each message you receive from the APRS SPEC.

APRServe seems to be operating better today.

However, I noticed that a packet sent to first.aprs.net, and third.aprs.net does not get echoed back to the sender. A packet sent to second.aprs.net gets echoed back as expected.

Why the difference between servers?

The answer lies in the title of your question. Only second.aprs.net is
APRServe, a Macintosh program I wrote and the original hub. The other two
run aprsd. Technically the title should be "APRS Internet System
question".

aprsd does not echo sent data back to the originator, while APRServe
does. Personally I think it is better that the sender see their data
echoed, I don't recall the reason Dale chose not to...

Ok, thanks. My expectation was that when connected to a server I would see all data that the server was passing. This is something that needs to be looked into. The echoing of sender packets confirms that the packet was indeed accepted by the server.

Reality, or my ideal? The former is going to be impossible to document.
My idea of how it should be is three servers at the center, each
interlinked with the other two on port 1313, and every other user and
IGate connected to one of the three with a verified connections on port
23/10152 (most IGates and users not desiring buffer dumps on connect),
port 1314 (IGates desiring the smallest bandwidth, or 10151 (users
desiring buffer dump)).

>2. The present APRS network bandwidth requirements should be analyzed.
>Many of the sites and connectivity are provided to APRS at no cost. We
>should
>attempt to limit the impact that our activities have at these sites.

>

At this time it is very manageable, running about 50k bytes/sec at all
the sites, about a third of a T1, and all except www.aprs.net have a
better connection than that.

>3. The APRS bandwidth requirements and effects on local RF links should be
>analyzed.
>Local RF issues are local issues.

I agree, so why is this analysis part of the IGate process? From the
beginning it has been the policy of the internet system not to impact
upon the local LANs. aprsd provides the possibility to negatively impact
the network if misconfigured, while APRServe doesn't give those sort of
options. That is a philosophical question that the new aprsd author will
need to decide. Personally, I was happy with my decision to hardcode the
potentially QRM causing parameters to prevent problems.

>The APRServe network should provide a
>highly
>reliable feed to IGATES and accept data from verified users. Existing
>verification procedures should be examined, documented, and new methods
>proposed.

>

This is a biggie. A decision has to be made whether to secure the stream
at all, and if so, some robust scheme needs to be developed and
implemented. Not a task for the skittish!

>4. The proposed specification should incorporate provisions to permit the
>exclusion of data that is not APRS compliant.

On this count I favor less rather than more. The only check APRServe performs is that a line looks like a packet, roughly 3-9 chars followed by a '>' followed eventually by a ':' and at least 6 chars of data, total length less than 250 bytes. This eliminates much of the garbage without being overly restrictive to changes.

>These provisions, if implemented by a server would eliminate any packets
>that
>are not recognized as APRS compliant packets.

The problem is that the spec is not static, any substantive change means updating all IGates before the new format can be used. While ideally people would update their software regularly, there are many users with very old versions out there.

> Servers would have the
>option of
>performing limited cleanup of APRS packet headers to remove non-essential
>TNC
>display formatting, rather than rejecting the packet outright.

Something to consider...when I was maintaining the system, something I would have killed for is an ID of the exact path a packet took through the internet system. My eventual plan was to have each IGate strip off any unused digis in the path, then add the callsign of the station which sent it to them (rather than having each IGate add their own call), providing traceability of the packet. With a strong verification system, it would make it simple to track offenders.

It's time to start playing with aprsD. Echoing received data
(optionally) is near the top of the list. Any other enhancement
requests?

Stirring the pot a bit.

> My idea of how it should be is three servers at the center, each
> interlinked with the other two on port 1313,

Why only 3? Why not an unlimited number? 3 will be overloaded. It's
only a matter of time.

>and every other user and
> IGate connected to one of the three with a verified connections on
> port
> 23/10152 (most IGates and users not desiring buffer dumps on

Port 23 is telnet. There are reasons (firewalls) to use it for a
server but it's something that should be discouraged.

>
> >4. The proposed specification should incorporate provisions to

>
> On this count I favor less rather than more. The only check APRServe
> performs is that a line looks like a packet,

That's good. Maybe make a separate port for the non-spec packets.
Trash the real garbage. Pass packets that are close.

We also need a scheme for passing experimental packets under the
guise of APRS.

> Something to consider...when I was maintaining the system, something
> I

> would have killed for is an ID of the exact path a packet took
> through
> the internet system.

The originating TCP system could flag the packet with
something like NWPTCP-1* instead of the current TCPIP*

> My eventual plan was to have each IGate strip off
> any unused digis in the path, then add the callsign of the station
> which sent it to them

Another good idea.

Why don't we either use aprsspec or set up a new mailreflector
for discussing this. Make it an OPEN discussion OPEN to
everybody concerned. Build a spec from the consensus.

Bill

I'll run some data captures of the current servers this weekend from work.
Unless someone has additional suggestions I'll do the following:

- 1 - feed data capture - capture the actual information coming across the server links (after passing through the daemon and as it crosses the wire)
- 2 - take packet traces (via tcpdump) of connect, disconnect, and data injection
- 3 - take packet traces (via tcpdump) of the same actions via the various client programs I've got available.
- 4 - dig through the APRSd source for the raw network I/O code to see if there are any gotchas hiding.

I'm open to suggestions and will have just about everything except a Mac available to test on.

I know people probably won't like these suggestions. They involve updating software, using newer computers (I.E. less than 5 years old) as key network nodes, and improving the network. That said, I'm going to suggest it anyhow. ;)

I believe the concept that "everyone needs all the traffic" is not beneficial for APRS - or any other high volume linking network. Hopefully, the technology we develop here can be used on the radio waves as well as the internet!

Why does my APRS client at home care if N7F00BAR is talking to KC7BARF00? I might care about his position report, but probably not his messages.

Granted, most of the APRServe backbone traffic is simple posits, but I bring this up because of the damage the current system is doing to the RF network. (I run an Igate, and think the damage is better than going without the service, but I would prefer to operate in a slightly more professional manner)

Reality tells me that more than one user will run an Igate in a small area. True, we shouldn't do that with the current network, but it happens. I'm surprised if I see less than three Igates gating messages into my local LAN (and I only gate if I hear the person within one digi hop - I may even turn all outgoing gating off). This can and should be reduced.

What I propose has been done on almost every other packet network outside of APRS. The Internet does it this way, as does IPX, and most commercial packet switching networks. We might be able to learn from these.

Basicly, I propse ARIP. This would be similar to RIP on the Internet, but

with the modifications needed to work on APRS. This would also allow messaging to work efficiently with more than one

The packet format on the IP network would be different than it is now. It would consist of 16 (this should be enough for now) 32 bit numbers (yes, this would increase the size of the packet - but bear with me - it will decrease the loops and such greatly). Each of these numbers is an IP address, which work like a "Received From:" header in an Internet mail message. This will allow easy detection of loops, and also of too many hops (any packet with all 16 slots "filled" gets discarded).

In addition, each packet contains a "secondary network hop count". This would be the RF hop count, as best as could be determined. The "total" hop count to the station could be easily determined by adding this number with the number of IP addresses.

Of course, the APRS packet would also be included in this message.

When a NODE (not an end user) receives a packet, it would look at the "total hop count" and see if the total hop count for that sender was less than the total hop count a local "routing table" (which expires every 30 minutes or so). If it is, it updates the routing table with the IP of the downstream destination - which we know is closer to the source station.

There would also be a special "Routing Information Packet" which says, effectively, "the routes I had for stations X, Y, and Z are no longer valid."

If a packet is found for which there is no known route, it would be sent to all IGates.

This way, when a non-broadcast packet (messaging) is sent, a node could look at the routing table, decide which station seems best, and send the packet there. It would allow transparent backup functionality to the network. If 10 people run igates, only one would get any particular packet to gate back to RF. If someone lost their IP connection, that route would be removed by the Routing Information Packet, and, shortly, new routes would become established.

>only a matter of time.
>
Three is a number adequate for the present level of traffic, and given
that all three are on connections greater than T-1, they can handle
roughly 6 times the present level of traffic.

If you are suggesting that everyone become a central server, this is
asking for trouble. First, the number of interconnections rises rapidly:

1 server 0
2 servers 2
3 servers 6
4 servers 12
5 servers 20

more generally $(n-1)*n$.

Next, as long as the software allows user-configurability, the governing

group must verify each server is correctly configured. Manageable with three stable sites, very difficult with 100 or more.

Finally, each time a server is added, all the others must update their interconnection lists, another administrative nightmare.

```
>>and every other user and

>> port
>> 23/10152 (most IGates and users not desiring buffer dumps on
>> connect),
>
>Port 23 is telnet. There are reasons (firewalls) to use it for a
>server but it's something that should be discouraged.
>
Well, discouraged is a relative term. Do you really want to cut off an
entire class of users? Many people at least work behind tight firewalls
that block non-standard ports like 10152. Port 23 is almost always open
to outgoing connections, allowing these people to participate in the
system.
```

What is the harm in this that it should be discouraged? At the central sites, owners must move their telnet connections to another port, which takes 10 seconds. None of the other users care what port telnet is on. A nice side effect is that telnet, the most common hacking port, has a little security through obscurity.

```

Well, it turns out that TCPIP* is important, it shows that the packet came from a verified station. If you eliminate this, you must provide another means to flag unvalidated packets (or eliminate validation altogether).

Being a map oriented person, I always thought this would be fun to do. A live NETWORK map drawn in real time showing geographically the links that were currently operational. Glad to see it on your list...

I disagree strongly. The everyone-gets-everything paradigm is central to APRS in general, not just the Internet portion, at is in large measure responsible for its success.

>

>Why does my APRS client at home care if N7FOOBAR is talking to

And yet the message page is the third most popular web page (after find and weather) on findu.com, with 3000 views in the last week alone. "Reading the mail" is a time-honored tradition in ham radio, and clearly popular. While it is clear you don't like it, it is what has made the internet backbone so very popular. It is important to leave room for what other people enjoy in APRS as well as what

Well, there is no reason that messages should get passed from the internet to rf unless the recipient is "local" (generally 2 or less digi hops), and the sender is not local. If you are seeing this traffic, then it is due to a misconfigured or incorrectly coded IGate.

>Reality tells me that more than one user will run an Igate in a small

This is a matter of local coordination. One of the ideas I had considered, but tabled as too complex, was to have each IGate look for other IGates and not transmit if they are not primary.

Instead, what was planned to eventually get implemented was for an IGate to generate a random few second delay when it has a message to send, and listen first. If the message is heard on RF within that time, it means another IGate has sent it, and therefore the other IGate will not send it. A special case of no-delay could be added for a "primary" IGate in each area, but of course if you do it, there is one more parameter for the operator to mis-configure ;-)

Exactly. This is what I had wanted so that we could use the PATH as the loop filter, and trace agent. As it is, we use the 3rd party format identifier which makes any other use of the 3rd party format unworkable via an RF-INTERNET path. Just a thought to put on the "future" list.

Couple thoughts:

All opinions are my own and open for discussion --

1 - our first task is to document the current transport protocol interactions as they exist today.

2 - in parallel (although hopefully secondary for the folks working on #1) we can examine various methods of crafting an APRSServe V2.0 (just made that up) protocol suite. The protocol suite itself might just expand on the interaction between servers and the interaction between servers and clients. (I know that "server" and "client" can get a bit fuzzy, but its the closest I can get)

As part of this exercise we might think of the the server software as consisting of several modules

(note: this is a reference model)

- IP network transport - make sure we get the bits from A-B in a consistent format
- Session control - some type of capability determination and request/response mechanism for data
- Authentication - challenge/response and who is allowed to do what to whom.
- AX.25 inbound filtering - what do we send to IP
- AX.25 outbound filtering - what do we send from IP
- IP inbound filtering - what do we accept from connected machines (support for machine/class level configs)
- IP outbound filtering - what do we send to connected machines (support for machine/class level configs)
- stateful packet parsing engine - able to determine packet type and possibly other data (hopefully most of the work is already in PerlAPRS)

I'm thinking about a session control protocol that would go something like this:

Client/Server (or server/server) -

1. client initiates connection request to server
2. server checks IP rules to see if client is allowed to connect
3. client authenticates with server
4. client and server negotiate client's desired data vs. server capability
5. server and client exchange data according to #4
6. server or client can initiate graceful disconnect

4 - the heaviest detail will be involved in #4. I think we need to thrash around a bit on what level we want to negotiate down to. Some possibilities:

- only within X nm radius of point X

- only weather reports
- only messages (or no messages not addressed to stations not on this connection)
- etc, etc, etc

Sounds like loads of fun to me!!!

73/N5VFF (actually M/N5VFF/P until I get a UK ticket)

Loops are easy to prevent by proper configuration, I don't think we need
it for loop prevention, but regardless I do think it is a good idea.

If each hub connected to two or three other hub's, everybody
would get everything. Why should all the hubs have to connect
to all the other hubs? Make it a true mesh network. It would be
possible for areas to "break off". That would have to be considered.

> Well, discouraged is a relative term. Port 23 is almost always
> open

> What is the harm in this that it should be discouraged?

No real harm beyond the fact that it makes the hubs non-standard.
Does hub 2 also support 10151 in parallel with 23? The more
consistency there is between systems, the better!

> Close is a relative term. What do you mean? I generally oppose

Close is what you described.

> Well, it turns out that TCPIP* is important, it shows that the packet

Of course. Wouldn't a scheme that provides both validation info AND
identify the originating IGate be a good thing?

>

I'm here now, but had long ago unsubscribed from this list.
As this got started on APRSSIG, I'd recommend you post that
the discussion has moved here as I see no reference to it
on APRSSIG.

Personally, I'd rather see a independant list focused on the task at hand but whatever works. This is, or was, the TAPR sponsored WG "peanut gallery" list, and until we know its status, mixing the groups might confuse the issue. I'd most certainly ask their permission to host here if your going to stay.

Of course, the new list should be open access and not private like the previous TAPR WG list was.

I just wrote down some things I'd like to see in a draft

outline. I am sure I missed some things. Please add what is missing.

Thanks

Jeff

We really have three tasks here.

1. Document what exists so someone can develop applications for it.
2. Document need ommisions and fixes (to both server and clients) (*)
3. Document extensions (**)

Don't forget we do need to get on paper what exists as well as what needs to be fixed and what needs to be extended. Here is my view on it:

OVERVIEW of APRSERVE network (use Steve's papers)

BASIC STUFF

Connecting to the server (basic port numbers)
Decoding posits (reference to APRS protocol document?)
Client verification (source code snippet)
Enter posits

MESSAGING

Overview (use Steve's paper)
Sending messages (APRS protocol document?)
Recieving messages
Internal server communication (port numbers ect)
 Message passing
**Extensions to messaging
 RF message gateway selection
 Least hop routing
 Least power routing

FILTERING

Message Dup's (source code snippet or structure description)
*Non-compliant packet filtering
**Geo-Filtering
 By feed
 By client (might be OK on smaller FAST servers)

CLIENTS

Connection to the server, rules

Messaging rules

- I see you, you see me, (flood broadcast)

- **Who are my RF neighbors

- **What are their RF footprints

- **List of stations nearby (lat/lon)

- **Least power routing

- **Server selection of gateway message station

Client gateway rules

- *Only gateway APRS compliant packets

- *No protocol conversions done on gatewayed packets

- *No math conversions done on any gatewayed frames

Future extensions/fixes (framework for developers, not set in stone)

- Go over justifications for extensions and food for thought.

Anyways, that is my laymans view of it.

Agree. While I'd question to infinity, 3 clearly is too small of a number, even for just the U.S. let alone the world. If the number is going to be statically fixed, then you want to make sure you have one directly downstream

of each network hub (Chicago, Washington and San Jose). Then of course other continents/counties should have them near their major switch sites.

Agree 100%. I believe the IETF (that right?) assigns port numbers and while we may not need a specific assignment, we shouldn't co-op other adopted port numbers. I think anything above 1023 is fair game with some exceptions.

Yes, agree 100%. Trying to find all the documentation as it exists now is tedious at best. Should be a document that 90% of experinced developers can use to develop a application with no questions asked. The system is actually fairly simply.... this task will be alot easier then the over the air spec.... but locating all the info can be challeging.

> 2 - in parallel (ahthoug hopefully secondary for the folks working on #1)
> we can examine various methods of crafting an APRSServe V2.0 (just made that
> up) protocol suite.

Also agree 100% here. Bill Diaz through his hard work has found a number of "warts" in the system. As we document I'm sure we will find more. The APRSSERVE system, unlike the client base, is fairly small in numbers. Hence getting everyone to update will be far easier and we have no need for a legacy mindset. So why put it off?

Isn't that how the NOS convers servers do it? I know at one time they had
a nice map made up of the entire convers server network... I'll need to
see if I can find the link to it.... I think the fellow doing MFNOS was
behind it.

: > only a matter of time.

3 centralized servers (or some other magic number) could very well be appropriate with some caveats.

- 1) No client connections.
- 2) Load-sharing/balancing. ergo: nearest server routing. Basically a hierarchy to distribute outbound traffic. These server should learn something from an IP routing protocol whereas they only send data to "registered neighbors" who have connectivity via a qualified path to the source and/or destination station. This WILL reduce load network wide.
- 3) Lets NOT forget about the bigger portion of the network: RF similar features for dissemination of data between nodes needs to be created.

: Agree 100%. I believe the IETF (that right?) assigns port numbers and

Yes. Without going into ad-nauseum detail, it would be difficult to obtain a "well known port" assignment unless we subject ourselves to writing a IETF draft/RFC-like document.

: while we may not need a specific assignment, we shouldn't co-op other
: adopted port numbers. I think anything above 1023 is fair game with
: some exceptions.

Well known ports, both UDP and TCP are assigned through 1023. You are correct that anything beyond those ports is fair game up to 16,535 (could be

wrong on max...rusty).

Further, I really think the widen-n routing scheme was a great start in the right direction. There is no reason why the network couldn't have a bit more intelligence to determine nearest neighbors. It will always be a "broadcast" packet by nature of radio. But if this intelligence is coupled with some sort of compliance checking algorithms to determine that a neighbor is truly APRSSpec compliant can't hurt.

How many times have each of you found someone who just loaded any of the APRS software programs, and configured themselves as a WIDE and as such, reduced the overall coverage of your local network? It's happened around here before. Until someone NOTICES that someone is being a WIDE with 5 watts at 20 feet, it can be strange.

Finally, I know many of you have seen my posts with regards to the spec. I want to go on record however saying that I firmly enjoy the capabilities of APRS, and am willing to step up to the plate to help whenever possible. That being said though...an ounce of paranoia isn't a bad thing. There are people out there, and yes even in the amateur community that can/will take advantage of other folks hard work. I didn't want any work on the APRS spec to suffer any such fate.

For the record... I'm a data networking engineer, and would like to try to apply some of the rulesets of making wireline networks more robust to the APRS spec.

I've heard these same arguments applied to the end users. They
are even more specious when applied to server sysops. You would be hard
pressed to do much of anything on the internet with software/hardware
that was older then 3 years let alone 5.

Or look at it another way, what does that 5 year old computer hardware
cost? \$200 at a used computer store? If a guy can't afford that, he
certainly can't afford the internet bandwidth to be able to function
as a server. If you want to run with the big dogs, it costs money.

I have an idea for verification: use public key cryptography (on the Internet side only of course).

The RSA public key encryption algorithm is now in the public domain so:

0. APRS Verifier creates a permanent public/private key pair.
1. Each APRS User generates a public/private key pair.
2. Each APRS User submits public key, call sign, and maybe some dough (a couple of bucks, maybe via PayPal, to show they are serious or compensate the APRS verifier for bandwidth, server h/w, support) to the APRS Verifier's website.
3. APRS Verifier checks the APRS User's info. If it is up to snuff, signs the APRS User's key with it's private key, and sends a "pick-up-number" to the APRS User.
4. APRS User uses pick-up number to retrieve signed-public key from APRS

Verifier's web site.

To be verified.

1. APRS User connects to an APRS Server.
2. APRS Server sends a "challenge" to the APRS User
3. APRS User signs "challenge" with private key, sends signed challenge and verified signed public key back to the APRS Server.
4. APRS Server decodes "challenge" with APRS User's public key , proving it came from that user. Checks APRS Verifier's signature with the APRS Verifier's public key, proving that APRS User has been verified.

(I think there is a better way to do this, but my copy of "Applied Cryptography" is not at hand).

Advantages:

- Prevents Spoofing
- Can have several APRS Verifiers

Disadvantages:

- Adding Cryptography to existing APRS clients could be difficult (although public available crypto libraries are available for most languages/platforms).

(sound feasible ?)

A lot have folks have *talked* about what they would do. Some have even *analyzed* some of the problems. But before I judge the current system, it would only be fair to draft a new "spec", write a different client side, write a new server side, invest in the hardware, find someone to help with the T1 backbone, host a site for folks to download the install and help documentation (and registration) -assuming they meet the min h/w req'ts, and monitor and debug it for a while.

As mentioned, it's more user errors than system weakness.

What we've built to now doesn't seem so bad then, and look at the effort it took!

Thanks! Most of military projects don't turn out so well.

Our first priority should be documenting the existing network and how it presently operates. Steve has provided much of the needed information and insight into the many of the design decisions. Others have supplied much useful information.

We need a volunteer to compile information provided by Steve into a single document. Who is willing to accept this responsibility?

The network improvment postings have covered quite a bit of ground. Suggestions for network improvements seem to fall into 2 general categories.

1. Improvements to the existing network.
2. New network design.

IMO, initial improvements should be limited to those that would preserve the ability of existing client applications to function without change. A second phase could focus on improvements that provide additional services that may require changes to existing client applications.

Perhaps we could start a new thread that would focus on proposals for the next generation network? Of course, a new network design would require that APRS application developers agree to make changes to take advantage of the design.

Using port 23 is, in my opinion, a horrible idea. The only reason it's running on third.aprs.net is so I'm conforming with first & second, and even then it's a redir to 10152. There's no way I'm going to allow aprsd to run as root just so it can bind to a privileged port we shouldn't be using in the first place.

Personally, I think we should have our own list for this discussion.

To that end, I've created one. I'll leave it up to you all to decide if we use it, but you may join by visting this URL:

<http://www.ohioaprs.net/mailman/listinfo/aprserve-wg>

The list is open to anyone.

Just for kicks, I've also created an APRS WikiWikiWeb, which might be useful for documentation, or it might not.

You can check it out at:

<http://www.ohioaprs.net/wiki/>

Given that this list is called APRSSPEC, and the discussion is about an
APRS SPECification, I would have thought that it was an absolutely ideal
place to discuss it.

As I said, I'll leave it up to you all. I thought this list was for "the"
APRS Spec, and perhaps a forum dedicated to the APRServe topic
would be appropriate.

Well, I thought the discussion was about a proposed specification for
the APRS internet server network, which I would class as an APRS
specification. But perhaps this list was only supposed to be for THE
APRS spec?

Neil,

Your proposal should be considered for the next generation network. Perhaps this discussion and items related to the next generation network could be contained in threads dedicated to this purpose.

Would be beneficial if we could use subjects that indicate if our posts relate to improving the existing network or a new network.

Subjects similar to:

RE:[aprsspec] New or RE:[aprsspec] Improve

Could be used to permit SIGGERS to view the posts that may be of interest to them.

Regional servers or hubs could be employed to provide end-user connections.
This is presently done to a limited extent but should be expanded. Initially,

this could be implemented without changes to the existing network.

IMO, this would be appropriate to consider for the next generation of network.

Let me explain again about the network load. Two servers on T1 lines were close to maxing out. Now there are three on much fatter pipes. To say that the load could grow six time present without strain is being conservative. Will there be a six-fold increase? Maybe someday, but it is years and years away. Sure, we could put in 1000 servers now, and cover the day when every human on the planet will be on APRS, but that seems a bit of overkill. It took more than 4 years for the system to outgrow the original 2 servers on T1, during the most explosive growth of APRS (which has tapered off significantly), I expect the three server system to continue for a similar period of time. I think looking 4 years down the

pike is more than adequate in this case...

>3) Lets NOT forget about the bigger portion of the network: RF similar
>features for dissemination of data between nodes needs to be created.
>

OK, if by this you mean selective routing on TCP, I disagree strongly.
APRS exists on a one-to-many paradigm, the internet is the ultimate
expression of that, with one-to-all. For those that don't want it all,
there is Bill's excellent AFilter and AServer, but most people want to
see everything, the volume is not yet overwhelming even to a modem
connection, people's pipes are getting fatter much faster than the stream
is growing, I really don't see the need...

That's exactly the reason it is best to have all the servers conenct to each other. Otherwise it is necessary to develop some way of making sure each packet is completely distributed within the network.

If you have some other arrangement, then a physical loop is possible. In this case, you must now develop an alternative method of preventing looping. You become dependent of every programmer developing code that exactly matches the protocol. An error could bring down the entire

network. I think the present arrangement is better, where it is not physically possible to create a loop (except by misconfiguration, and again I'd like to see that prevented by aprsd the way it is by APRServe).

No, APRServe (and first.aprs.net for that matter) do not support the dual ports.

Regional is a difficult term to identify on the internet. From
www.findu.com to www.aprs.net is 3 physical miles, but 14 hops (through
Chicago and Dallas) on the internet. second.aprs.net is only 10 hops from
findu, but the path is direct (and the ping time shorter). This is hardly
a unique situation...

For people that do not want the full internet feed there is AFilter and
AServe. However, I think that things do not warrant creating a complex
network with more layers than is necessary. A single group of central
servers is more than capable of supplying the present load, now and in
the foreseeable future. KISS!!!!

>

First, I only asked the new first to move to port 23, because that is where it has been on APRServe almost since the beginning, changing it would have meant a lot of changes to user config files. I'm glad you did this, it makes it less confusing, but it was not required. The central servers have had different port arrangements for the last year or so, since I moved www.aprs.net to linux.

Second, please explain what is so horrible. True, it's not "pure", but how would you feel if you lived behind a restrictive firewall and this was your only way to get the APRS feed? I have to deal with this at work, the hospital blocks all non-standard ports, but it allows 23. I know I'm not the only one (I wasn't facing this at work when I moved the port to 23, this was done for other firewalled users). It's not ideal, but as you've shown, you needn't run as root to access the port, though most people do run aprsd as a daemon...

John,

Ok, thank you for your support. TAPR provides many needed services to the digital community, and these lists are much appreciated.

Many AFilter users run the distance filters almost wide open. Others use it to
limit the feed to provide regional data only. This can be particularly
important in countries that charge Internet fees based on the volume of data
downloaded.

Regional hubs that connect to the APRS core servers could be configured to provide APRS data feeds tailored to users needs. This could include GeoFiltered data, weather only, etc. Regional hubs could provide limited or expanded services without placing additional burdens on the core servers.

Selective routing could be implemented at a regional hub if desired. There would be no need to provide this capability in the core servers. IMO, they should be dedicated to providing a reliable and consistent feed.

Hello to the list,

A couple questions:

Could there be different streams? A National stream and Regional streams?

Could the basic Time,Date,Call sign info could be used for filtering?

Would IGates be able to filter messages so that dups are cut down to maybe twice?

Could the GHz portion of the Amateur Radio spectrum be used for IGATE radio traffic, cutting down the APRS 2meter traffic??

Is or could the National traffic,in text form,be posted to a web site for downloading??

(I hope my questions have not been too far off track for the group.)

Roger and Group

I'm going to ask that the group accept a request that "internationalization" be one of the (many) issues foremost on our collective minds... as this and future "SPEC" efforts go forward....

I for one am a bit ashamed that the US is in the same group with Brunei and Yemen as the holdouts in Metric and similar standards (day/month/yr being one of those other "international" standards)...

I have certainly turned off some in the US with my comments about keeping a world perspective in mind... not just US... and it's not been my intention,
but at the same time... we really ought to make at least a token effort...

I'm running it as a daemon, it just doesn't run as root. The fact that I
found a solution to avoid running it as root makes it less painful, but
it still bothers me somewhat. I guess I'm all for purity. :)

Great John. Glad to see the TAPR support. One thing I would like to see, if possible, is a "work area" so we can drop files for everyone to look at. I've got a bunch of notes and files I'd like to drop in it. Is there a APRSSPEC ftp file area? This is raw unpolished stuff.... just work files.

Thanks

Jeff

I was agreeing with someone else. Also understand the message I was replying to, and you apparently are making "mine", contained some FUTURE thoughts. I think this is great, but we do need to get down on paper what exists now. I think this should be our FOCUS and not getting into these holy war tangents.

That much being said, here is my spin on it. Understand that there may be a difference between regional servers and master servers.

1. The internet is not a homogeneous network.... it is not a big fat ethernet pipe. It has choke points around the world and the country. While I know some of you have all you can eat internet feeds, it is not that way around the whole world nor realistic for the whole of the U.S. Further, we need to be good internet citizens. Having 100's of client connections going across a less then optimal (in some case) internet backbones is not the way to do it, if at all possible. You put the servers in the same internet cloud as the clients, if at all possible. Even if NOTHING changed today, IMHO, the present server network should be set up this way. It is just a no-brainer. I understand the Canadians have actually done something like this already.

2. It would be wise, but not required, to model the typical regional server on ~128K feeds (ISDN) as not to many folks have a T1 in their back pocket. Understandably, this will reduce the number of client side connections each can support, but with a greater number of servers to chose from, this may not be an issue.

3. The poster whose message you made mine was referring to "mesh networks". He I believe was thinking of the NOS ConversD network, which is quite similar in basic function to the APRServe network, proceeding it by some years. However it's internal architecture is quite different... it was designed from the ground up to be able to run on lesser connections then are required for AprsServe. As it is somewhat decentralized, failure at a node point is not catastrophie. It also has limited abilities to actually route around bad nodes. Not entirely error proof, but one can typically safely go away for the weekend to the second home without to much risk. But I am aware this is not how AprsServe is set up today.

I can go on with other reasons, but don't want to get to far off topic. Your might considering querying the person that originally posted the message.

For now, I'd suggest we do the following:

1. Get down on paper what we have now.
2. Look for errors and omissions.... serious problems that need to be fixed or improvements suggested.
3. And then we can talk about some extensions.

Sound like a plan?

73

The thought "3 clearly is to small of a number" seems very much to be
your opinion, but regardless, my comment was directed at the opinion, not
at you personally. I asked you to explain why you felt that way.

The concept of regional is meaningless in the present internet topology.
As I explained, the path between my two servers is longer than between
findu and socat. Even if people in Miami were to use one of my servers,
many of them would still have their packets blasted at least through
Atlanta, if not much further away.

I would love to have made a European, Canadian, or Australian server
third.aprs.net, but none volunteered. That they are all US is not
US-centrism, but rather the result of no volunteers elsewhere.

This is very much unrealistic. ISDN is 64 or 128 k bits/sec, roughly 8
feeds. If a server interlinked with three others, it could only handle 5
users. A minimum of 50 servers would have to be linked, an administrative
nightmare.

>1. Get down on paper what we have now.

I have no problems with this.

That was quick ;-)

I uploaded the following files to Jon's system (above) and also the
upload directory of APRSSIG on TAPR. The TAPR files will need to be
moved someplace so people can access them. They are as follows:

aprsdDOC.htm (HTML docs for APRSD)
aprsdTCPportfunctions.htm (Port defines for APRSD)
aprsserve_dcc.html (Steve's original paper)
inetmsg.html (APRS messaging)
valid.html (User validation)
validation.c (C source code+ msg, which I should have called password.c)

Nothing new here, just getting it all in one place. Some of this stuff can just be cut and pasted.

Comparison tests were conducted of the data provided by first.aprs.net (aprsd) and second.aprs.net (APRServe) to see if there were any appreciable differences in feed content.

2 separate sessions of AFilter 2.03.7 were used to simultaneously connect to first.aprs.net and second.aprs.net. Each AFilter session used strict error checking. All packets that failed AFilter strict error checking were logged to disk. The test session was conducted from Feb 17, 15:16CST to 16:16CST.

AFilter strict error checks may log certain APRS compliant packets as errors.

Therefore, the files will contain perfectly compliant packets that do not, for various reasons, meet the requirements of the current AFilter sessions. These packets were not included in the detailed error analysis.

AFilter total errors reported. All errors.

	First	Second
	751	468

The error logs were examined to determine if aprsd and APRServe had differing results in the types and quantities of errors reported. Large discrepancies are noted below.

Explanation of errors reported :

Data errors : Packets less than 9 bytes or greater than 399 bytes in length.
Packets that do not contain greater than or colon.

Header char errors : Illegal char in header, improper formatting of header.
Originating call too long.

Header dest errors : Destination call is WIDE, [invalid] or other invalid call type.

Msg Length : Payload of APRS message type > 84 bytes.

Error type	First	Second
Data 72	0	
Header char	27	2
Header dest	70	0
Msg length	253	75
===	===	
Totals	422	77

Further studies will be conducted to confirm or refute the initial results.
Future studies will also examine the links between servers.

The errorlog files are available if anyone is interested in obtaining a copy.

Following the recent discussions about the use of APxxxx destination addresses in the APRSSIG, unless anyone has any serious objections, I intend to use APU1xx for 16 bit UI-View and APU2xx for UI-View32.

In both cases xx will represent the version number multiplied by 100 and then converted to base 36. E.g. version 1.79 would be 4Z.

That leaves lots of APUxxx options available for other applications, should anyone else wish to use them.

I was reading the chapter of the spec on implementing the Mic-E data format. I came to the following on the last page of this chapter, page 56:

===

Some parts of the Mic-E AX.25 Information field may contain binary data (i.e. non-printable ASCII characters). If such a packet is constrained to the APRS network, this should not cause any difficulties.

If, however, the packet is to be forwarded via a network that does not reliably preserve binary data (e.g. the Internet), then it is necessary to convert the data to a format that will preserve it.

Further, if the packet subsequently re-emerges back into the APRS network, it will then be necessary to re-convert the data back to its original format.

===

I actually think the current APRS network will have more problems with the Mic-E format than the Internet! As far as I can tell, the only special characters transmitted are ASCII characters 28 and 29 - and then only in Beta Mic-E's.

True, ascii 29 is often a control character for telnet. But, it is only a control character when hit from the keyboard of an interactive session - it can be received just fine.

Ascii 28 poses no problems.

Even though we have APRS servers on port 23, it is an 8 bit clean link, as it doesn't run the telnet protocol (like most port 23s), so there is no

quoting or conversion necessary. There is no operating system that I know of that doesn't implement an 8 bit clean TCP/IP sockets (otherwise, FTP wouldn't work). I've observed MANY control characters on APRSServe, and none seem to crash any of the servers (although some clients crash when they see "unusual" data - but they do this on RF, too).

Converting these MIC-E messages is a nice thought, but unless a conversion method is specified, it won't work. Too many people will convert them too many ways (sound familiar?).

So, here's a proposal for the WG to look at, vote on, whatever:

This paragraph should be changed to "Any network that causes ASCII characters 28 and 29 to be converted may not be suitable for transmission of MIC-E formatted messages. Software should convert these beta MIC-E messages. The conversion procedure is to replace character 28 with "\034" and character 29 with "\035" (the octal equivalents preceded with a backslash). These messages MUST NOT be sent in converted form into APRS Serve or the APRS network. When sending into either of these networks, the software must convert these characters back into ASCII characters 28 and 29 to allow duplicate packet detection.

===

An alternative, if the working group thinks the above will cause too many problems:

The Beta MIC-E format messages are currently deprecated and may not work across some third-party networks. Gateway software should drop, rather than convert, these packets if they can not be sent across the transit network.

===

I would appreciate the WG reporting on what happens to this small proposal. This is NOT a APRSServe proposal, but a proposal to change the actual APRS spec.

(This message is posted on the APRS SPEC SIG on a monthly basis.)

PURPOSE

The purpose of the APRS SPEC SIG is to provide a forum for folks interested in discussing the APRS protocol specification.

POSTING MESSAGES

To post messages to the APRS SPEC SIG, send email to aprsspec@lists.tapr.org

APRS SPEC SIG RULES

The APRS SPEC SIG has a few simple rules:

- . Be courteous. Abusive, insulting, or rude behavior demonstrated towards another list member is a violation of this rule.

- . Stick to the subject, i.e., the APRS protocol specification. Subjects that are only tangentially related to the APRS protocol specification (like "what kind of printer should I buy to print out my copy of the APRS specification?") may be considered off-topic. If you start a message with "this is off-topic..." then you are violating this rule.

- . Be succinct when composing a message. (The APRS SPEC SIG software has been optioned to limit the length of each message.)
- . When quoting a previous message, only quote the parts of that message you are referencing. (The APRS SPEC SIG software has been optioned to limit the length of a quote.)
- . Do not send messages in HTML or Rich Text format.
- . Do not send attachments.
- . Cross-posting is not permitted. (The APRS SPEC SIG software has been optioned to prevent cross-posting.)

Can someone please explain the differences between the different numbered APRS servers. I notice a different data stream is coming from each one.

The differences have been explained several times, consult the archives of this list and aprssig for details of the differences. In brief, the two servers run different programs. They differ in filtering capabilities, but in terms of viable data, they should all have the same data, though the ordering will be different.

hi

would anybody know the aprs settings [vhf] for the KAM [6.0 ver] ALL
MODE TNC ? and also the PK-88 aprs settings ?

i'm using WINAPRS.

thanks

73.

I'm not a WinAPRS user (you should know that from my .sig), but I
have run PK-88's on APRS a bunch.

Whatever you do, make sure that "mfilter" is disabled on it,
otherwise some of the non-printable MIC-E format characters will
end up getting filtered at the TNC and never making it to your
computer.

I think "mfilter 0" is what kills the filtering (tells it to filter

Just thinking it might be handy to have some internet remote control of the
stations that
are gating.... basically a remote control that allows you to disable gating if the
station
is out of control and/or out of spec. Filtering only treats the symptom of these
problems,
and in fact cannot address all of them.

This would need to be written into the GUI's and applications that function as a
gateway.
Someone trusted would need to hold the passcodes.

Just thinking out loud how I might address the above problem if I was in a
position to
do anything about it. Feel free to file this in the round folder.

-Jeff

It's not hard to do Jeff ... just don't allow them to connect to the server they are flooding / feeding with inappropriate data. That way everything can be in APRSd, instead of upgrading lots of WinAPRS (and still having the buggy WinAprs 2.4.6 out there) ... it would be almost trivial to have the daemon check the IP of the box requesting a connection before forking a new process.

It occurred to me today that testing for APRS compliance would be easier if a "test" file was available. If it were accompanied by a check list, the APRS author could verify the results produced by his software to determine conformance to the spec. You couldn't verify all aspects of the software this way, but it would be a great start.

Hello,

I'm currently programming for the XASTIR APRS software and came along some unknown formats received from Kenwood TM-D700 radios.

They seem to use '~' for messages and acknowledges, the message end character too is not '{' but '~' and there is a binary instead of 'ack'.

The data type '~' is defined "Do not use - TNC stream switch" in the current version of the PARS Reference document.

Is this problem known? Is everyone implementing his own rules and tells us he is APRS compliant? Should I implement messages this way?

Thanks and 73s
de Rolf

They're UI-View format messages. They're not coming from Kenwood radios.
(I wonder why you think they are?) They have to relevance to the APRS
specification.

Hello,

> They're UI-View format messages. They're not coming from Kenwood radios.
> (I wonder why you think they are?) They have no relevance to the APRS
> specification.

Thank you Roger for pointing me to that, I thought those guys are
using TM-D700. But it could be, that they use their Kenwood
transceivers only in the car and use UI-View at home.

I now ignore that data frames. Should I do something useful with it
or is it only used for communication between two UI-View stations?

I would ignore it. I don't think there's any point in supporting it in other software.

A few thoughts:

- o First, there needs to be a generally accepted understanding of what "APRS compliance" means. For example, does it mean "this implementation conforms to the APRS specification", or does it mean "this implementation passes a certification test suite that Bob Bruninga talked about creating"? I strongly favor language that differentiates these two concepts, perhaps "compliance" versus "certification".
- o Second, what does it mean to "conform to the APRS specification"? Does an implementation need to correctly receive all formats in the specification, or just some? Does an implementation need to be able to transmit all formats in the specification? Can a tracker ever be "APRS compliant", since it can't send messages?

I believe that it would be useful to create different classes of APRS devices (analogous to what are often called "profiles" in other standards work). That way, a tracker could be "APRS compliant" if it conforms to the tracker profile, without having to have a graphical user interface.

The APRS specification never cleanly separated protocol issues from user interface issues. I believe that this will tend to confuse discussions about "APRS compliance". Is an implementation "APRS compliant" if it conforms to the protocol specification, but not to the commentary in the APRS specification about user interfaces? (Personally, I think it was a mistake to include user interface issues in the APRS protocol specification, largely for this reason.)

- o Third, it would be very useful for a third party (i.e., not the developer of APRS code) to determine APRS compliance. During the development of the APRS specification a number of developers said things of the sort "No, the specification must be wrong, because my code does it differently."
- o Fourth, the development of a good test suite is a very tedious process. Plus, this difficulty is likely to be compounded by complaints from developers whose code fails a particular test. On the other hand, this is part of the maturation process for any protocol specification. The specification is, in some sense, tested every time two parties discuss whether a particular format or sequence conforms to the specification. Perhaps, the result of these discussions is that the specification is incomplete, inconsistent, or vague, and needs to be enhanced.
- o Finally, there is the issue of whether developers particularly care whether their implementation conforms to the APRS specification. I believe that during the development of the APRS protocol specification one or more developers said, more or less, "I don't care what the specification says, this is what my code is going to do." <Insert long, extended debate about advantages of open source implementations here, or not...> <Insert another long extended debate about the importance of interoperability of APRS implementations here...>

A freely available test suite, plus a publicly available compilation of test results would, in my opinion, be a very good thing.

And, without a good deal of care, will not be usable to test some
programs, if they do not normally process the typical, simplistic,
monitored data output from a TNC.

The TNC/PC interface is, from the perspective of the APRS protocol specification, an interface internal to an APRS station. The APRS protocol specification should make no reference to this [internal and optional] interface (although I haven't reviewed the spec with this topic in mind).

I believe that it is far more appropriate for an APRS protocol test suite to be expressed as raw AX.25 frames (which reflect the objective of the protocol specification, namely to specify correct on-the-air formats and protocols).

Of course, this leaves the challenges of representing on-the-air AX.25 packets (I believe that the TAPR TNC2 THN/Host interface is a poor choice) and getting the test packets into an APRS implementation (if I had time, I would try wiring two 1200 bps TNCs or modems back to back to see if they would transfer packets).

> Again...(I keep saying this over and over) this is not to say that
> BEACONet is better than APRS...it's just different...but not so
> different as to keep APRSdos and UI-View users from participating if
> they so choose.

>

> Regards,

> Ev, W2EV

Even WinAPRS (still the most popular software) and the Kenwood radio operators could participate if you changed your "BEACONet Protocol" just a little bit. That could greatly increase BEACONet's acceptance, Ev, and I believe it would be well worth the effort.

You write at

<http://www.rochesterny.org/beaconet/information/BEACONet%20Protocol.txt> :

BEACONet(tm) To-Call Field Parsing (vers. Alpha.08):

A Destination-call or To-Call of CQ or BEACON may be used. When done so, it should be understood as a valid BEACONet frame, with station information "undisclosed".

Otherwise, the embedded information in the To-Call takes the format of BSNPAH-D where:

B = Band from Table 1
S = Sub-band from Table 1
N = Network Function. See Table 7 and associated notes.
P = Power Output (not ERP) from Table 2
A = Antenna Influence from Table 3
H = Height Above Average Terrain from Table 4
D = Directivity from Table 5
<snip>

The 3 Bytes that cause your proposed incompatibility with some software and the Kenwood radios are the first two characters of the AX.25 Destination Address (which your protocol uses for "transmit frequency" info, "B" and "S"), and the SSID which you use for "Antenna Directivity" ("D").

All except B, S, and N can be relayed with the use of PHG (which even WinAPRS understands) as in other AP* flavors.
What about the idea of keeping your B, S, and N in there using something like
APbsn
and using PHG for the other info.
Maybe even throw another letter in there after the AP to specifically designate BEACONet. Looks like B is still available. Then it would be APBbsn

This small change would eliminate all incompatibility with ALL the flavors of software AND the Kenwood radios.

Since you already state that a "valid BEACONet frame, with station information undisclosed" is allowable, why not make this small compromise to allow so many more people to participate?
73, Cap KE6AFE

Actually, no. Part of the spec, the "third party format", makes the TNC
text external to the station. Even a hypothetical client program that
only operated in KISS mode is still going to have to have the capability
to parse the TNC text format.

>I believe that it is far more appropriate for an APRS protocol test suite

To the best of my knowledge, all APRS programs accept the text format of
input. By "raw AX.25 frames" I presume you are proposing a new file
format with just the binary data, correct? TTBOMK, no APRS program
accepts this format. Therefore, in order to use the test suite, each

author must add code to their program, code which is otherwise worthless, and could be another source of errors. Alternatively, someone must write programs to transmit the info on the air (or two TNC's back to back). This would allow people other than the programmers to perform the test, but requires setting up hardware.

If it were a TNC text file, click open and you are testing.

What precisely do you gain by using this format other than being more pure?

Programs may be able to parse "TNC text format" embedded in a third party frame, but that may not be the format of the input to the program. The input to the program may be KISS frames, WA8DED host mode frames, etc. You cannot use "TNC text" as the input to a program that is expecting to see KISS frames, on the grounds that somewhere in its processing it can handle that data. To handle "TNC text" as the program input would require compliance testing to be done on a special version of the program with some sort of input "hook" added.

Even if the program uses a TNC in terminal mode, and accepts "TNC text" input, it may choose not to take the "normal" approach of discarding the frame type information before it leaves the TNC. Therefore input like "G4IDE>APRS:Information field goes here" may be discarded.

I am aware, and stated, that you cannot feed TNC text into a program that is expecting KISS mode. My statement was that no program accepts input exclusively in these modes, to the best of my knowledge.

Are you saying that UIView does not work with a TNC in text mode? I will admit that my experience with your program is extremely limited, but I'm surprised your users haven't asked for that feature, if for not other reason than to import tracks retrieved with the findu rawposit script.

If your program does accept this input format, do you know of any other program that does not? Even if yours, or another program will not, how hard is it to add that, since you already must process the format in the third party packet?

Compare that effort to that required of every author to support a new file format.

And again, what does the proposed format provide that a TNC text format does not?

It supports terminal mode, but to accept the simple format I quoted, and
the format you are presumably referring to as "TNC text" -
G4IDE>APRS:Information field goes here
Is an "only use this input format if you really have to" option.

It's not a problem for me, because I'm well capable of putting together
an input converter to read the TNC text, and output it as UI KISS
frames.

However, as development of APRS compatible software outside the USA hopefully increases, this problem is likely to affect other apps. There are parts of the world where the "normal" TNC is, for instance, a TNC2 with WA8DED/TF firmware.

So I'm only expressing an opinion on what I think is a desirable format for test data, not pointing out an insurmountable problem.

[snip]

>Compare that effort to that required of _every_ author to support a new
>file format.

I don't quite see it like that. If someone is going to make the huge effort to produce a "test suite", I would have thought it was better to provide a reference set of KISS frames, that can be very easily converted into any input format the author may require. A binary representation of a frame is a more reliable definition than something that has supposedly come out of a TNC2 with a particular set of parameters configured.

>And again, what does the proposed format provide that a TNC text format
>does not?

See above.

Did I miss something? Isn't most of the APRS Spec based on the "simple" terminal
format?

Yes - but I think we should also test the program's ability to deal with unusual control characters in the data stream, since it happens in real life (TNCs break, people do compressed mail transfers on 144.39, etc)...

I agree with Steve, the text mode format is an easy to read text file
that can be parsed by hand and characters counted. If you had a
binary format test suite, it would require special programs to
create, edit, and view the data. Since its purpose would be to test
APRS programs, using an APRS program to view the data would not be
sufficient.

I disagree with this. WinAPRS supports both normal TEXT mode TNCs and KISS mode. Additionally it supports AGWPE, in all 3 cases, the parsing code converts the "frame" into an internal format before any "APRS" parsing begins. This is the part that separates out the source call, the destination call, the digis, etc. Therefore the test suite from a NORMAL text file test the SAME parser as other modes use. The difference is I do not have any code to read a "binary" kiss mode file. Even if you were to have a KISS mode file, you have issues as to if it has the fill characters inserted or removed.

If a particular program needed to use KISS mode files. I would expect that author to write his own program to convert normal text mode files to KISS files for ingesting into the program itself. The "official" files need to be easily read by anyone with a text editor.

Would it be a useful thing, if I was to create a small box that output
APRS-Talk, in both correct and munged form?

I'm thinking an AVR (because I prefer them) Max232 chip, and not much else,
which could be reloaded with new firmware by anyone at near zero cost.

I'd need definitions of properly formatted messages, and I could have it

spit out "canned" errors, as well as randomly bash a byte or two in each message. It would look like a TNC to the program.

It could even be made to accept commands like a TNC, though that adds another layer of complication.

Since the first half (correct packets and canned errors) would be absolutely repeatable, it should make testing very simple. If the authors feed me any problems they pick up, then I can put that in to the next rev, as a specific test.

My only question would be rom capacity, might have to add an external EEPROM if the canned part gets too large, which would take a second layer of no-cost programming to reload as needed..

If succesful, we could end up with a cheap and repeatable way to verify compliance.

The way I do it is much simpler, I hook 2 computers to each other via a serial port. On one, I run APRS (Mac or Win) on the other, I use a terminal program to dump the text file out the serial port. I can now send any of the 100's of log files that I have (most from debugging user reported problems) to the program for a real "live" simulation. I have even done this using 2 serial ports on the same computer. Either way, it works well, costs nothing, and I can send what ever files I want.

Ok, that works for me..

Do we need web space to host these test files?

The concern I have with this:

How do you test the Ham Hud 3 with it's internal packet modem?

Other than this, I really like this idea, and it seems clearly the way to do it.

I might suggest, though, that you look at the Palm Pilot. Not only could it send the packets just fine, but it could ask questions like, "I just sent a message from N7XUC-13 to N7XUC-1. Does the program alert you to this? <YES/no>". I can't think of any other way to test things like message reception (yes, it acks, but did it actually receive it?) and bullettin overwriting (newer bulletins overwrite older ones).

The hard part of this isn't the Palm Pilot programming. The hard part is the script the program runs.

I propose the following "language" for writing a script. If someone writes a script using this language, I'll test it.

(I don't know if I got the packet format right)

(note that I quote *'s - since * becomes a wildcard)

T Messaging Test

S N7XUC>WIDE*,APZCRT::N7XUC-1 :Test Message {322

E 60 N7XUC-1>*:N7XUC :ack{322

P Did the "Test Message" I just sent display properly?

R Yes

R No

C Yes

"T" is the command to start a text. One argument is given, the name of the test (so it can be put on a report).

"S" means "SEND"

"E" means "EXPECT". It takes two parameters, a timeout in seconds and what it expects.

"P" means "PROMPT". It asks the user a question. It takes one argument, the question.

"R" means "RESPONSE". This is only valid following a "PROMPT". Each of these gives a valid response.

"C" means "CORRECT". This is the answer that SHOULD be given.

If any one of these fails, all the other "S"ends should be sent in that command and no "E" or "P"s should be processed until the next "T".

My guess is that whether the software is accepting data from a TNC, IP, AGWPE or Text file, most programs will use the same parser engine, and it will be based on the "simple" terminal data formats found in the APRS Spec.

A text file is portable and easy to transmit, and I suspect most APRS programs have the ability to read them already.

The issue as I see it is documentable results. I can hang out on second.aprs.net for a month at a time, but unless I know what is SUPPOSED to happen I will probably miss some things. The real value of a test file is the accompanying document that describes what should of happened, i.e. a digi with a "N" overlay at this coordinate, an object at this coordinate with this symbol and this overlay etc.

I never proposed that the test file should be the ultimate test of APRS compliance. It it would be a great tool for developers who want to test their software against some sort of known standard.

Regards,

Rich - Wn0x

An internet server like aprsserve could stream out a test file for the PC programs (doesn't help much for things like radios with built-in APRS, unless you gate it back out to RF).

You could take it a step further and have the internet server send you message packets telling the operator to test a function of the program (ie beacon a position) and then send back a message saying that it was done correctly.

To test sending capabilities from radio's like the D700 you could send a message to the server saying "I'm about to test ... tell me if this is properly formatted" - then send your packet - then wait for a response back.

Hopefully what I wrote is coherent ... I woke up waaaay to early this morning.

How are these going to be created and edited? To do KISS frames directly,
you would either need to use a hex editor, which would be very tedious,
or write a custom editing engine. Anyone that wanted to look at the test
suite would either have to get the editing program, or go to the trouble
of converting them by hand. Seems like a needlessly complex method.

Since you are proposing to require a conversion routine to go from KISS
to text, why not write and edit in the more easily readable and usable
format, and convert to KISS for those few apps that need it?

Can you describe an instance that has any relavence to the APRS spec,
where the tnc-text would not be representative of the KISS format, and
could not be easily converted?

On Wed, 28 Mar 2001, David VanHorn wrote about the APRS test files.

> Do we need web space to host these test files?

I began a test file long ago, it takes a lot of work. Because each format

packet should be self explanatory. So that the viewer does not have to hand analyze each one to see if it is correct or not.

For example a COMPRESSED posit packet might include this text:

HEADER:POSIT-FORMAT..."This is at the Washington Monumnet"

Thus if its there, it worked. If its not there, its broke.

Just sending a whole bunch of packets is a waste of time, unless they are "self-proving"... That is where the creativity and effort is involved in building the test suite...

That's cool, but you could also have a file of data that is known to create
"problem X". You download it, play it to your system, and debug till not
"problem X".

You can also have large "wads" of correct packets in all their various
forms, which systems must accept without crashing.

This is where "categories" of APRS devices would be nice. My primary interest has to do with the way objects are displayed on maps, bulletins, watches etc are handled, so I am viewing the test from a slightly different perspective.

It is possible that the HamHud 2100 will have mapping, or the D7000AZ, but for now they deal with a subset of the spec. That doesn't mean they won't be entirely compliant with portions of the spec appropriate for those platforms.

I doubt anyone currently using any APRS software made their decision based on compliance, but instead based their decision on platform and feature set. I don't plan on marketing APRS software with an "APRS COMPLIANT" logo on box. Maybe a picture of Bob?

I am primarily interested in compliance from a tactical, decision support perspective. A developer should have some idea of how well his software supports this aspect of APRS design specification, and have a tool for determining if there is a problem and fixing it.

If I can't see it, or its in the wrong place, or doesn't accurately represent the situation...

In article <LYR13460-3347-2001.03.28-11.16.34--roger#peaksys.co.uk@lists
.tapr.org>, Steve Dimse <k4hg@tapr.org> writes
[snip]

>

>Since you are proposing to require a conversion routine to go from KISS
>to text, why not write and edit in the more easily readable and usable
>format, and convert to KISS for those few apps that need it?

One of the bits of my message you didn't quote said "It's not a problem
for me, because I'm well capable of putting together an input converter
to read the TNC text, and output it as UI KISS frames."

>Can you describe an instance that has any relavence to the APRS spec,
>where the tnc-text would not be representative of the KISS format, and
>could not be easily converted?

An obvious example is when the received frame isn't even a UI frame -
but I think that opens up a whole new can of worms, and the spec doesn't
really handle the situation, so I'll withdraw the comment... ;-)

You also ought to create large wads of incorrect packets, which systems ought to accept without crashing. (I believe that this is particularly true, given the emphasis that has been placed on the use of APRS in emergency situations.)

Yes...

A file full of hosed packets that caused problems in the past would be good
for regression testing.

This is exactly what I have been doing for years. I have a large collection of both good and bad files. In the early years, Bob and I shared these file and every time he came up with something new, he would send me a file. I would then work on code until it behaved properly.

I've seen over 25 postings on this subject.

Yet no-one asks the obvious question.

Who is going to do it?

~2 years ago, in its charter, the APRS-WG clearly outlined a verification suite along with the certification process for the product claim of "APRS Certified". So the need was clearly recognized at that time.

I think TAPR owes it to the amateur community either to replace the members on

the WG that resigned and once again jump start the group, or officially terminate the group. I know for a fact a number of people have volunteered to help out in various regards with the WG, both to replace the members that resigned as well as to start documenting other aspects of the protocol. Yet to my knowledge no action has been taken here.

The problem here is not one of blame, but one of the whole project is in limbo. Nobody wants to step on anybodies toes, hence the end result is not only that nothing gets done, but that those that would do something don't want to offend those that did by forming a new group to manage APRS.

It just seemed so obvious to me all these postings, while good and well intentioned, wouldn't amount to a hill of beans just as all the posts on the APRSSERVE protocol didn't amount to anything of substance. It is not the fact that no-one is offering to help, but that the whole process is in the twilight zone, at best.

Or am I mis-informed here?

-Jeff

If you look closely at the APRS WG charter, you'll see that it is not a TAPR-owned organization. TAPR has one vote on the committee, no more. While TAPR was important in the formation of the WG, it cannot accomplish either of the suggestions you make.

I have a slightly different take on why the APRS Internet Protocol went nowhere (I really prefer everyone stop calling it APRServe protocol). The APRS Spec exists solely because of the superhuman effort of one person, Ian Wade, who took the time to understand and document the protocol. I don't know how much time he spent on this, but I'll bet it over 200 hours.

Note that Ian was never a member of the APRSWG. He came from outside and made the enormous personal commitment required. When he did so, his efforts were greatfully accepted by the APRSWG. No one came forward to make a similar commitment to the Internet documentation project. If someone had, I believe the results would have been different.

I agree that all this discussion on the test suite is likely to end up just like the Internet discussion. Regardless of the number of people that offer to help, there has to be one single person that steps forward to coordinate all these volunteers (and in many ways more people make it tougher). In efforts like this, the coordinator ends up putting in far more work than any of the troops. This person could come from inside the WG, or outside, it doesn't matter.

To say "The APRS WG should take this task on", or "TAPR should make it happen" overlooks the reality that both these organizations are composed of individuals with their own time constraints and priorities. Should Bob be forced to do it? John Ackermann as president of TAPR (and the non-voting administrative chair of the WG)? One of the board members of TAPR picked at random? A callsign picked out of the callbook? Who has the power to force these people to do it? Even if you could, the results would be poor, an effort like this must be a labor of love, and so far, no one seems to be lusting after this task!

If someone did step forward, make a serious proposal to the APRSWG, and back it up with the requisite effort, I bet they will find a warm reception, and I wouldn't be surprised if such a person were offered a spot in the APRS WG.

In case some people don't recall, I'm not a member of the WG any longer, and I speak only for myself on this issue. I do not have the time or inclination to take this task on. Perhaps someone out there does...

You missed the point, but I'll try anyways

Steve Dimse wrote:

>

> TAPR-owned organization.

It is on the TAPR web page, it was commissioned by the then TAPR president, and to this day I see TAPR officers taking credit in TAPR's name for the good work documenting the APRSSPEC.

If I looks like a duck, quacks like a duck and smells like a duck, I call it a duck regardless of any wiggle room that was written into the charter that you are quoting to us.

In any case, I am not casting aspersions, just suggesting we call a spade a spade. Does the WG still exist?

> TAPR has one vote on the committee, no more.
> While TAPR was important in the formation of the WG, it cannot accomplish
> either of the suggestions you make.

Can't or won't? Being TAPR created the WG, I see no reason why they could not jump start it if they had the will and desire to do this.

> Note that Ian was never a member of the APRSWG. He came from outside and

That is not how I understand it.

> I agree that all this discussion on the test suite is likely to end up
> just like the Internet discussion.

OK, at least we agree here, although possible for different reasons.

> To say "The APRS WG should take this task on", or "TAPR should make it
> happen"

When did I say this? You really need to read what I post instead of what you want to hear. I'm simply stating if the APRS-WG has ceased to exist, that needs to be stated. It is fairly clear to me that another protocol committee needs to be formed, yet the existence of this ghost protocol committee is a potential negative factor. Being you feel that Ian Wade was the only contributing person of the old WG, and I understand he has resigned, I would think you agree the WG has ceased to exist. A indeterminate state is not a positive thing and I know at least one potential motivated volunteer it has discouraged due to them not wanting to rock the boat.

What I *did* say is TAPR owes a commitment to the amateur community. This goes beyond any legal loopholes you have cited here. It appears to me that a validation suite is both wanted and needed and we both agree with the current situation, this is unlikely to happen. Stepping outside the legal loopholes, it appears promoting such a thing is within TAPR's mission plan.

> If someone did step forward, make a serious proposal to the APRSWG, and
> back it up with the requisite effort, I bet they will find a warm
> reception, and I wouldn't be surprised if such a person were offered a
> spot in the APRS WG.

1. Serious proposals have already been made to the WG, with the requisite effort, and I know you are aware of this. At least one of these persons was a serious player.

Yet nothing apparently came of it. Which leads me to the obvious question of...

2. Does the APRS-WG still exist?

Anyways, just to stay focused, I'm just suggesting that all good projects need conclusions, and this one does as well. It certainly doesn't mean by officially acknowledging the disbandment of the existing WG anything will happen... to a lesser degree I share your cynical attitude, yet the existence of this ghost group is a discouragment/distraction to the formation of any other group.

-Jeff

I gotta quote Jeff exactly here or he's going to whine more, although I did cut out a few lines so he'll retaliate anyway!

>>What I *did* say is TAPR owes a commitment to the amateur community... It appears to me that a validation suite is both wanted and needed and we both agree with the current situation, this is unlikely to happen.

>>the existence of this ghost group is a discouragment/distraction to the formation of any other group.

Does anybody else disagree with these two? A lot of folks have undertaken the development of software and other initiatives on their own and shared it with the APRS community without the endorsement, assistance, or participation of the WG. Most of the time, it was because they *WANTED* to do it by themselves, and got whatever assistance they needed from email, web sites, and asked for a few snippets of code where necessary. If there are some of you out there being held back by this ghost WG, "BOO" on you!

The APRS WG members continue to appear to welcome anyone who seriously starts to put effort into a project, as long as it doesn't add more to the workload of what they already still incredibly find the time to devote. And APRS is still being expanded in a lot of directions. The authors are doing a pretty

good job of certifying and testing their own work (if not for pride then to keep the complaints down.)

A certification algorithm is a good idea, yes. And, if it were a GREAT idea, it would have been done by now.

Seriously, is "TAPR" going to say to Bob et. al. and say "Sorry, guys, you're not doing enough. We're firing you and opening up seats for a new group" ? Heck, we never even refilled Steve's seat :-)

I think there's plenty of room and goodwill for anyone who wants to pursue an aspect of APRS that seems weak or needs to be better explored. No one is stopping anybody, and certainly not the WG.

But, let's take a moment to check out what's been done accomplished recently.
Sprouls fixing up the UHE's and other things self-discovered
Steve's keeping findu running and improving
APR Bob's sat tracker hardware and software
Mike's new release of Palm PocketAPRS
Barker's PSK31 work
HamHUD next generation
TinyTrakker economizing
APRS+SA enhancements
Ev's Beaconet data
Mark's Citadels and other hardware projects
And heck, that's just off the top of my head.

Thanks, everybody - I think we're doing pretty well for a bunch of "amateurs"
!

The APRSWG came out of a meeting that was arranged and largely paid for
by TAPR. It was organized by Greg because of an ongoing dispute between
Bob and myself over the future of APRS. The specific issue was ownership
of the protocol, I was fighting for an open spec that would be open to
all programmers. TAPR's interest was in nuturing APRS, making sure it
didn't die because of the dispute.

In forming the working group, TAPR was very careful to avoid both the
appearance and the substance of "taking over" APRS. APRS is Bob's baby,
and he has every right to have a big say in its future. Hence the reason
that he gets two votes, this was one of the least contentious issues we
covered. The working group was set up as an autonomous entity quite
deliberately. This is not wiggle room. TAPR does not have a right to
control the APRS WG, or APRS in general. Only the APRS WG controls the
APRS WG. Sure they get web space and a TAPR mailing list, but so do a lot
of other projects over which TAPR has no control.

When I said that the spec existed "solely" because of the efforts of Ian,
my words were poorly chosen. Many people contributed, and I certainly
wouldn't want to shortchange John for his role of
moderator-with-the-patience-of-Job. What I was trying to convey was that
even with Ian's incredible effort, it took much longer than anyone

expected. Had Ian not been involved, it would never have been a finished document.

TAPR can certainly claim credit for creating the working group. And just as a parent gets to claim a share of credit for the achievements of their offspring, TAPR has right to be proud of the APRS Spec, it wouldn't exist without them (and without Ian, Bob, TSB, et. al.). But as every parent knows, children grow up, and you lose control over them. The APRS WG was born full-grown, and TAPR had no control (other than their single vote) from that point on.

>In any case, I am not casting aspersions, just suggesting we call a spade

AFAIK, yes. Will it ever do anything useful? Personally, I have my doubts. I do wish they had taken my last recommendation before I resigned and appointed you to the vacant seat. I don't think the outcome would be any different, but you'd have an understanding of the difficulty in getting even this small group of very busy people to do anything.

TAPR does not have an official policy on this, I'm speaking for myself, but I honestly don't see what TAPR can do. As I said, this is a group of very busy people, none of them have the time to do the leg work of creating an Internet document or a test suite.

That sure sounds like you are saying TAPR should make his happen by jumpstarting the group. And you certainly seem to be saying that the APRS WG should be doing the test suite. My point is that "The APRS WG" is a group of individuals. AFAIK, none of them have the time or inclination to do either the internet document or test suite. Is there someone out there willing to take either of these tasks on? If so, I haven't heard of them...there are a lot of people that want to help, but none willing to shoulder the primary responsibility. One needn't be in the APRS WG to do this, though if someone was putting out the kind of effort Ian did, I would most definitely attempt to get the board to have our rep nominate the person for membership in the WG. Further, I would try to convince the other WG members to vote in favor. However, before I do something like this, I need to see someone accept the challenge, and do some serious work.

Over the last year, I've had perhaps 20 people come to me asking to help code things on findu. For each I've given my source code, accounts on my system as needed, and support. I've spent a lot of time walking people through things. Total lines of usable code returned to me: 0. So forgive me if I'm jaded, but before I throw my recommendation to someone, I want to see results.

>I'm simply stating if the APRS-WG has ceased to exist, that

If Ian was a WG group member, it happened after I resigned. I don't believe that was likely, because by the time I left, he was pretty burned out on working with the group.

OK, so exactly what would you have TAPR do? We don't have control of the
WG. Even if we did, and we completely restaffed the WG, what would that
accomplish? My most important point in the last post is that there needs
to be another Ian, one that just gets the job done. Not someone that
proposes to get it done, not someone that wants to help, but someone that
does it. And they don't need to be in the APRS WG. If someone does it,
I'll bet the APRS WG supports it. And if they don't, who cares? It will
still be there, useful to and appreciated by a lot of APRSers.

I know of no such effort. Who has produced a start on either the internet
protocol or test suite?

I simply was stating that we have already had a discussion like this before,
and it seemed ashamed to spend so much time on it when we had no outlet
for it. Even Steve Dimse agreed with this. I saw 25+ posts on the need for
a validation algortim, and I was pointing out this simple fact.

> The APRS WG members continue to appear to welcome anyone who seriously starts
> to put effort into a project,

I'm not talking about the past, I'm talking about now.

Does the APRS-WG still exist? It is a simple question. If it doesn't exist, the
a new group should be formed to address the needs the posters are indentify.

Real simple.

> Thanks, everybody - I think we're doing pretty well for a bunch of "amateurs"

Again, the accomplishments of the past was not the point.

-Jeff

Yeap, saw all this.

Also think it was a big mistake and stated so at the time. APRS needs and needed a firm standards body. I thought it should have been TAPR. I never agreed with the kissy face approach to it... and I believe my feelings are being borne out. With any standards body, you need to have firm control of the protocol. Protocols are NOT open source, they ultimately have to be dictatorships. Personally, I'd rather see Bob grab it back then what we have now... a benevolent dictator is far far better than anarchy.

OK. Fair enough. Your child grows up, turns 18, and you loose control of them. Yet when they are 19, you get a call from the hospital or worse yet, the morgue, do you tell the state they are on their own? No, you help them back on their feet. This was the role I was suggesting here. I understand it is not your legal responsibility.... yet clearly the child is sick. Either sign the death certificate (or stop saying they still exist) or help them get back to health.

> >In any case, I am not casting aspersions, just suggesting we call a spade
> >a spade. Does the WG still exist?

Yet of all the times this has come up, I only recall Bob saying they still existed. You of course are no longer a member yet still seem to get involved in everyone of these discussions.

> Will it ever do anything useful? Personally, I have my
> doubts.

Doubts or hopes?

> I do wish they had taken my last recommendation before I resigned
> and appointed you to the vacant seat.

Yes, you mentioned that you had suggested me and Tim Salo, yet I only heard this from you. I found this strange when I knew of far more qualified

people then myself that had actually volunteered. And they were not accepted. While I have volunteered 11 separate times over the last 10 years for TAPR projects (and I am 0/11) this project I did not volunteer for. That is not to say I wouldn't have accepted if called upon, yet that didn't happen nor did anyone on the WG acknowledge to me you did what you said you did.

- > I don't think the outcome would be
- > any different, but you'd have an understanding of the difficulty in
- > getting even this small group of very busy people to do anything.

Part of volunteering for any project is having both the skills, interest and time to contribute. This is something I have taken into account every time I have volunteered. If someone doesn't have the time to contribute, they should resign. So if such was the case on the WG as you outline, with mostly disinterested parties

onboard, I would guess you would be correct as one motivated person couldn't make much of a difference, in particular if they met with resistance.

- > >Can't or won't? Being TAPR created the WG, I see no reason why they could

Force the issue. Mentor the group back to health or sign the death certificate. Simply follow TAPR's mission plan would be good. Steve Jobs didn't say I told you so when Apple was in trouble, he came back and helped the company get back to health.

- > As I said, this is a group of
- > very busy people, none of them have the time to do the leg work of
- > creating an Internet document or a test suite.

Then help them recognize they don't have the time, and resign their seats so those that volunteered can fill them. Ego's will have to be stroked in that sometimes recognizing your limitations is a attribute and not a negative.

It is not mine to share. I just know otherwise. Being you are not omnipresent, I fail to see how you can dispute this. You'll just need to take my word on it.

Yes, I said the part about jump-starting. I think this is what TAPR did when the group started, and if the group is sick, it is justified and well within TAPR's mission plan.

> And you certainly seem to be saying that the APRS
> WG should be doing the test suite.

Did I say that? Don't recall, but this written document stated that as well:
ftp://ftp.tapr.org/aprssi/aprssi/aprssi/announcements/APRSWG_charter.pdf
so at worst all I am guilty of here is reading the above.

> My point is that "The APRS WG" is a
> group of individuals. AFAIK, none of them have the time or inclination to
> do either the internet document or test suite.

Yet TAPR and them signed a document stating such. I'm *not* demanding they do as such, I'm just suggesting some closure here might be of benefit. I know you like to harp on how no-one volunteers, yet this whole issue is volatile. Look at the responses so far and how charged it has gotten so quickly. And for someone to form a alternate group when the "existing" APRS-WG still is on the books? My spin on it is either fix the existing WG or clear the decks so another group can be formed.

> Is there someone out there

> shoulder the primary responsibility.

What, you hope if you say that enough it will be true? Sorry, but I know of at least two well qualified people that volunteered to fill your empty seat

on the WG without a response from the WG.

> However, before I do something like
> this, I need to see someone accept the challenge, and do some serious
> work.

You mean like Bill Diaz? He has put hundreds of hours into debugging and writting helper applicatiосn (and now AHUB) to fix protocol violations on APRSSERVE.

> >What I *did* say is TAPR owes a commitment to the amateur community. This

> OK, so exactly what would you have TAPR do?

Force the issue. Mentor the group back to health or sign the death certificate.
Simply follow TAPR's mission plan.

> We don't have control of the
> WG. Even if we did, and we completely restaffed the WG, what would that
> accomplish?

You have already indicated there are people on the WG who don't have time for it. Just like you wouldn't accept people on the TAPR BOD who don't have time for it, the same should apply to any group. A volunteer organization is a very tricky thing.... people typically volunteer for a reason, often it is wanting to contribute and also receive recognition for their efforts. Managing the volunteer organization is even harder. As people's "compensation" is not monetary, you have to recognize people's motivations. Resigning can be a honorable thing... it doesn't always have to be a resignation in a huff or flaming certain members of the group. The role of the TAPR leadership should be to promote a friendly changing of the guard, be it within TAPR or their satellite organizations.

> still be there, useful to and appreciated by a lot of APRSers.

I posted a outline of a APRS internet document. I seem to recall, no-one,

including yourself or anyone on the WG, made any comments on it when I first posted it. So it is not as simple as "building it and they will come" no matter how many times you say it. Not only do you have the need for people to volunteer, you also must have the ability to accept newcomers. The patient is simply sick and a decision has to be made.

> >1. Serious proposals have already been made to the WG, with the requisite

AFILTER was a excellent start along with the discussions, documentation and volunteer efforts surrounding it. But of course, you knew this and have chosen to overlook it.

Listen, my point here was not to start a pissing match. My point here was to remind everyone posting the 25+ comments on the validation suite that unless we clear the table first, their efforts may be in vain.... something you appear to agree with.

The only thing I remember you posting was a summary of information you gained largely from docs I had written. If there was something else you posted please remind me. In any case, I'm not shy, if there was something in the doc I felt I should have commented on, I would have.

Again, AFilter, as good as it is, is an implementation of the APRS spec, not the Internet spec. The document is the hard part. Technical writing with clarity is very difficult. I can't do it, from what I seen neither can you. It is a specialized skill, one that is none-to-common.

"Volunteering and DOING" are two different things. The APRSwg has noted over and overagain, that it will welcome submissions of efforts on the APRServe issues and here on the protocol test-suite..

> It is not the fact that no-one is offering to help, but that the
> whole process is in the twilight zone, at best.
> Or am I mis-informed here?

If someone is willing to "offer to help" then just "do it". Everyone, knows what needs to be done, how to do it, and what form it should take. It only takes someone to DO IT. If such a "volunteer" exists, then I am sure that his efforts will be greatly recognized... and soundly endorsed by the APRSwg...

Volunteering means *doing something*, not filling a seat at a table.

> Part of volunteering for any project is having both the skills, interest
> and time to contribute...

You left off the most important point... "and doing it". There are
lots of people with the skills, and interest. The only proof of whether
they have the *time* is whether they DO SOMETHING or not.

I would far rather have a group of people that DO, than a committee of
kibitzers who only sit around and argue all day over opinions and do
nothing...

> If someone doesn't have the time to contribute, they should resign.

Similarly, if someone does not contribute anything, then they should not expect to be added to the WG..

I think the members of the WG have time to REVIEW and APPROVE an APRS Internet Spec and an TEST suite! But SOMEONE (I dont understand why this is so hard to understand) but SOMEONE has to put it on paper...

I agree completely with Steve. Anyone that puts all the APRServe ideas on paper or puts together a documented protocol test suite would be a PRIME CANDIDATE for addition to the WG! Such a person would be WELCOME!

> at least two well qualified people that volunteered to fill
> [Steve's] empty seat on the WG without a response from the WG.

Anyone can fill a seat. We want someone that CONTRIBUTES by DOING SOMETHING. Yes, we have had say a dozen volunteers. If we had accepted all of them we would have a rooom full of people and still not one single thing on the table to look at... Duh... whats wrong with this picture?

Bob & Steve:

Responding to both your posts in one as they are basically the same thing. I also need to remind both of you that APRS Compliance is not the APRS internet protocol. The only reason the internet protocol was brought up was as a example, not the specifics here.

Steve Dimse wrote:

> >It is not mine to share. I just know otherwise. Being you are not

Then that exactly what you will have to do.

The thread I was responding to was about APRS compliance, not the internet protocol document. You, like Bob, are not seeing the contributions people are making. This was simply a example of a contribution in response to your claim no serious work is being done. While it may not be to a Steve Dimse or Bob Bruninga level of competence, the claims both of your keep making that no-one is stepping forward are specious.

> APRServe and aprsd
> are not "a good start" on the Internet Protocol Document, are they?

Yes, they actually are. Take a look at WA4DSY's web page and the documentation. It lists all the suggested port numbers and some other useful information that didn't exist anywhere else. When I put together the outline I posted here some time back, I used this information in the outline as well as what I was able to glean off yourself.

<http://www.tapr.org/tapr/list-archive/aprsspec/0102/msg00024.html>

> Once again, TAPR has one vote out of seven.

I was talking about taking a leadership role for the betterment of packet radio, I was very clear about this. OK, here is a easier one for you:

Who are the seven votes? Roger Barker asked who the present members of the WG were some time ago, and met with silence. You apparently know, so who are they? I say the parrot is dead, what say thee?

> Again, AFilter, as good as it is, is an implementation of the APRS spec,
> not the Internet spec. The document is the hard part. Technical writing
> with clarity is very difficult. I can't do it, from what I seen neither
> can you.

What, did you review the paper(s) I did in my technical writing class or something?

I don't ever recall putting out a paper for publication that you would have seen. I did send you a outline draft (twice) of a internet spec, which I hoped you would comment on... is this your comment now? It was never intended to be a publication quality document, just to focus and stimulate discussion towards a goal, which it failed to do.

None-the-less, if you recall, the first cut of the APRS-SPEC was a far far cry from what we ended up with. If you keep seeking perfection, and running those down that don't meet you level of perfection, who will want to volunteer for the job?

> It is a specialized skill, one that is none-to-common.

Certainly. But in a volunteer organization, you need to take what you can get. Chasing those away that don't meet up with your standards seems counterproductive, if indeed your goal is to accomplish something.

Bob Bruninga wrote:

Yes, it does... speaking of seats, does the APRS-WG still exist (beyond just yourself)?

> I would far rather have a group of people that DO, than a committee of
> kibitzers who only sit around and argue all day over opinions and do
> nothing...

Who is doing this? I'm seeing quite a few "do'ers" in the prior thread, which was my concern. While you may think of them as "kibitzers", I think if this title fits,
it is by no fault of their own.

A process was put into place and this group was created to address that process. If
the process (in the form of the APRS-WG) is defunct or has ceased to exist (like the
parrot), then your right, it is "kibitzing". But how are people to know this
unless
you, as the manager of this committee, can be honest with yourself?

IMHO, it seems to me you either fix the process, as was intended, or you simply
state the parrot is dead so we can go get a new parrot. If you watch any Monty
Python, it is a real simple concept to grasp.

> > If someone doesn't have the time to contribute, they should resign.

>

> Similarly, if someone does not contribute anything, then they should not
> expect to be added to the WG..

Certainly. So you feel alot of "non contributors" have volunteered to be on
the WG? Just so we are clear on things, I was stating those that are not
or cannot presently contribute should resign. What matters is now, not any
past accomplishments, although I agree this should be a metric in choosing
someone. But ultimately, the ones seated on the WG need to perform. This may
require "taking a chance" with someone, but if you have a understanding those
that don't perform will be asked to step aside, I don't see this as a big
risk.

> I think the members of the WG have time to REVIEW and APPROVE an APRS
> Internet Spec and an TEST suite! But SOMEONE (I dont understand why this

> is so hard to understand) but SOMEONE has to put it on paper...

If you are having problems understanding it, I suggest you review the WG charter. Things are spelled out very clearly there. But I think the parrot is dead. This is what is not being understood. We either need to give the parrot CPR, or bury it.

> I agree completely with Steve. Anyone that puts all the APRServe ideas on
> paper

That was last month although similar concept.

> or puts together a documented protocol test suite would be a PRIME
> CANDIDATE for addition to the WG! Such a person would be WELCOME!

OK, this is the thread you are responding to. This is what the charter has to say about that:

6. The Group will put a voluntary APRS certification process in place, to be managed by Bob Bruninga with Group oversight. The process will include a publicly available validation suite.

So in effect, this can survive the death of the APRS-WG with you still in control. And that was what I was saying, that a benevolent dictator is far better than anarchy.

I know that Bob Bruninga is not a ghost and I know you have a active interest in APRS. Your stepping up to the plate through thick and thin. All I am saying here is that to keep the illusion alive that the WG still exists is counterproductive and ultimately will cripple progress.

Quick questions, how many additions to the protocol have been made in the last two years as compared to the prior two years? Get me point now?

> > at least two well qualified people that volunteered to fill

"Duh"?!? Alot is wrong with this attitude. Look at what you just said. A dozen volunteers have stepped up to the plate and volunteered. The two I know HAVE DONE SOMETHING. Yet you

assume none of them are worth anything. Maybe they are not up to Bob Bruninga or Steve Dimse standards, but the two I know are real players and know their stuff, and I fully expect the others are just as good. Yet here you are predicting the failure of these people. This attitude is what is wrong with this picture. Part of any volunteer groups charter should be to mentor new blood into a organization. Fact of the matter is, any successful volunteer organization does this. I'm not seeing this here and it explains alot.

Listen, we can go back and forth on this, but at the end of the day we will be worse off then when we started. Lets agree to disagree, OK?

To restate and retain focus as to my core thoughts:

I was reminding everyone that a formal process that once existed here no longer does. Hence the well thought out comments being made about the compliance suite could be wasted. I suggested that TAPR might be able to jump start that process, as they once did before....that doesn't appear to be in the cards. And lacking that or any similar effort, I thought it proper we declare the parrot dead so that its corpse would not get in the way of a new group being formed (not that it would.... just the ghost hanging around is a discouragement).

That is it.

-Jeff

For example of how difficult it is to get user input to the WG,
last week I requested inputs from anyone that is using any of the USER
DEFINED formats in the APRSspec. I was going to make a list that would
help everyone find unused combinations. Not one single response
from the SIG... And yet we know that there are lots out there...

So its not easy being on a WG, where no one submits useful work, and yet
everyone feels happy in complaining that no one else is doing anything...

Just a thought...

My appologies to the group. My comments about getting feedback from the
SIG was not intended to be a flame at all. Nor was it meant to condem all
the tremendous effort made by a whole lot of folks!

It was just a microcosmic look at the two simple APRSwg items that I am
trying to get finalized. 1) a list of TOCALLS and 2) a List of USER
defined formats.

Again, my apologies for my choice of words, I was probably subconsciously
reacting to all the flames pointed my way... while just trying to get
something done...

I know the feeling.... when I posted my draft outline on the APRS internet protocol, not a single person on the SIG commented on it. I even forwarded to one of the past players... not a peep. But it doesn't mean what you are doing is not needed, you just have to decide in you own mind the path you want to keep, and stick with it. Your doing the right thing.

Anyways, does the APRS-WG still exist? (as a group comprised of more then just yourself) Sorry to be so repetitive here, but I have asked this question twice of you now, with no response.

Sure what? That they still active or that there is a out of date member list on the

TAPR site that still lists members who have long since resigned? Be clear here please.

I wasn't asking if a paper list existed, I was asking if the WG was still viable. Viable

means actively meeting, setting goals, following the charter, having a puraility of

active members. You know, polly parrot is not dead and off pinning for the fjords.

If the WG is now only yourself, I personally think that is not a bad thing. We can get

some clarity and make some decisions. Use (or share the names of) some of those 12 volunteers to get the APRS compliance process going. Someone needs to record all the suggestions being made on the SIG... draw a outline up, start to fit the suggestions into that outline, Identify the testing conditions, ect. I'm sure

more then a few of the 12 people who volunteered to fill the empty seat(s) on the old WG would be happy to help. Heck, I'd even help a little if I knew I wouldn't be wasting my

time or having to herd cats. But I have taken on another APRS project more suited to my talents

so it would have to be limited. But I don't see this as a huge project anyways....the protocol

document is a great start. You and Mark have some test files. All that is really needed is

some direction and goals. Be it from you under the WG or if the WG has ceased to exist,

from some other project manager. But that could just as easily be you, if you so desire. I'd

vote for you. But I still feel reality needs to be acknowledged so we don't waste our time

serving ghosts.

So, is the APRS-WG viable?

Regardless of the answer to this question, if you and Mark Sproul could make available the

compliance test files both of you indicated you had, that would be a good start of something to build upon.

Sure. I just counted 157 Emails in the APRSWG of discussions regarding
all the things we are working on in the last 6 months. All members are
participating.

Good. Can you post a status update on the list then? Who are the present members?
What is the next thing on the agenda? What are all the things you are working
on in the last 6 months? How can people help you out? Would you consider releasing
the test file(s) you mentioned the other day?

Thanks

Jeff, did you mean to ask the WG _secretary_ to do that work for this
mailing list? hi

The files I uploaded to the TAPR site are now available. (and I think they have been for some time, just didn't check till today)
They are:

aprsdDOC.htm (HTML docs for APRSD)
aprsdTCPportfunctions.htm (Port defines for APRSD)
aprsserve_dcc.html (Steve's original paper)
inetmsg.html (APRS messaging)
valid.html (User validation)
validation.c (C source code+ msg, which I should have called password.c)

and are located at: <ftp://ftp.tappr.org/aprssi/aprssi/aprstcp/>

Nothing new here, but it does get every file in one place, when before they were spread over various web sites and embedded in peoples e-mails. If anything is missing, drop it up there. You would send it to:

<ftp://ftp.tappr.org/aprssi/upload/>

and then drop a note to Larry Keeran, K9ORP @ aprs-lib@tappr.org letting him know the file is there and where to move it to.

These are the files I referenced in the draft outline I wrote up last month. It hasn't been moved over yet to a public area, but if you want to compare the files to the outline it is at:

<http://www.tapr.org/tapr/list-archive/aprsspec/0102/msg00024.html>

I'm of the mindset that 50% of something is better than 100% of nothing, you don't need to be a polished technical writer to help here or even write anything original. In my case I was just a packrat and dumped what ever files I had collected from other people. It might be useful to go through some of the Q&A on the groups as well, and drop HTML images of those messages in. I did briefly, but not exhaustively (the validation code came from one of the newsgroups).

I know Tim, Bill, Gerry and certainly others have written some fairly good outlines of their ideas.... you guys might want to go through some of your gems and using Lyris grab the HTML code and drop it in the FTP area. Note there is no compliance area at this time.... just the old spec area and the APRSINET area.... but if you ask Larry he can set that area up. I don't have anything for the compliance area.

73

-Jeff

Who is the present WG secretary? As I indicated to Bob, the charter on the TAPR site is now outdated. While I could ask the present secretary (if there is one), Bob is alive and kicking and should know the answers to what I asked in the message which you were replying to. In any case, all the questions I have asked have been on this list, so one would think all active and interested members of the WG would see them. They were again:

1. If a status report might be made on the APRS-WG.
2. Who are the present active members?
3. What things has the group been working on in the time period mentioned in the e-mails?
4. How can people on this list help out? (small and large things)
5. Would Bob and Mark consider releasing the text compliance files they use in their own software? (this would simulate and focus some of the work, and would be a good upload to a yet to be created compliance area on the TAPR ftp site)

I guess I didn't consider the above much "work" and even if it was, it was "work" that only could be accomplished by those on the WG. Seems like a sentence or two on each item might suffice. Do you have a problem with the questions I asked? I didn't think they were out of line, although I don't like having to be so pushy and repetitive here. I'm just of the opinion we need to be honest with ourselves if we ever hope to get anything accomplished in a timely fashion.

> hi

OK, I believe this is a CW term for humor. So, maybe I need to ask for a clarification as your question did seem serious to me.

Did I misunderstand your question?

Thanks

Jeff

The WG charter and protocol (aprs101.pdf) both list Stan WA1LOU as the WG secretary. As secretary of my local amateur radio club (a voluntary position), I find that I'm often asked to perform many tasks that nobody else wants to donate the time and effort to perform.

No. I was only attempting to make light of the idea that you were asking someone (Bob) to perform a new set of tasks when the discussion here has recently been about whether there's someone who is willing and able to donate the time to perform similar work.

>

Yes. Perhaps I should have used <GRIN> instead of "hi" as the mode we're using here is email instead of CW. Please forgive the colloquialism.

>
> Did I misunderstand your question?

A bit. I was only half-serious. The other half was just trying to inject a bit of ("smart-aleck") humour. Sorry.

I wasn't asking Stan to do any work nor am I assuming a document that is not
current is accurate. I'm sure he and other members, if they still are active
members of the WG read this list and are capable of speaking up if they have
something to add.

> <snip>

This are the tasks I suggested:

1. If a status report might be made on the APRS-WG.
2. Who are the present active members?
3. What things has the group been working on in the time period mentioned in the e-mails?
4. How can people on this list help out? (small and large things)
5. Would Bob and Mark consider releasing the text compliance files they use in their own software? (this would simulate and focus some of the work, and would be a good upload to a yet to be created compliance area on the TAPR ftp site)

Now, the question I have for you is how can a newcomer or someone not on the WG address these tasks? While Bob may not be the one to answer these mostly simple questions, I would think you would have to agree someone outside the WG could not, correct? Are these not fair requests?

>> Did I misunderstand your question?

Hey, I am guilty of this as well. No need to be sorry, it should be me. It is good to step back. But I tried to tone down my dead parrot skit rhetoric in the last go around so maybe I was a bit too serious. ; -)

Correct. I think they are fair requests. If someone from the WG can, and

wants to, donate the time and effort to produce the answers to those questions and send them to this mailing list, they will.

Sure, if I could find it. I suspect it was on a previous PC that has long

since crashed and burned. Maybe Mark still has his?

I am in the process of making some text compliance files. These will
be a series of files and will probably be released as each is
completed and verified.

Maury

Mark's Sproul address is:

msproul@jove.rutgers.edu

The address listed for Keith Sproul is okay, but I would prefer:

ksproul@vger.rutgers.edu

Keith

Greg resigned as the TAPR representative. I remain in the non-voting moderator slot, and have been speaking, but not voting, for TAPR in the interim. TAPR will be appointing a new representative to replace Greg.

John

Now that the dust has settled on the "Protocol Compliance" thread (did anyone actually volunteer to do anything? <grin>), I wanted to be a "man of my word" and move the discussion of the BEACONet protocol here (at least the one that started on TAPR's APRS(tm) listserve).

I'll get right to the point: for those who choose to take the time to understand and research before expressing an opinion, they will find that BEACONet fits quite nicely into the existing APRS(tm) paradigm.

The BEACONet system was developed in such a way as to function in compliance with the APRS(tm) AltNET concept. Here's ALTNET's are: <http://www.dididahdahdidit.com/text/altnets.txt>

As an aside...APRSdos *will* decode BEACONet transmissions simply by invoking the following command: CONTROLS-FILTERS-OTHER to ON. This is noted at: <http://www.dididahdahdidit.com/text/protocol.txt>

Additionally, UI-View works for both BEACONet and APRS operation without needing to invoke/revoke any filtering.

According to the APRS Protocol Specification 1.0.1 (a 3MB file at <ftp://ftp.tapr.org/aprssi/aprssi/spec/aprs101/APRS101.pdf>):
Page 23 of 128...

"Generic APRS APRS uses the following generic beacon-style
Destination destination addresses:
Addresses AIR* ALL* AP* BEACON CQ* GPS* DF*

DGPS* DRILL* DX* ID* JAVA* MAIL* MICE*
QST* QTH* RTCM* SKY* SPACE* SPC* SYM*
TEL* TEST* TLM* WX* ZIP*

The asterisk is a wildcard, allowing the addresss to be extended (up to a total of 6 alphanumeric characters)."

Page 25 of 128...

"ALTERNATE NETS Any other destination address not included in the specific generic list or the other categories mentioned above may be used in ALTERNATE NETS (ALTNETs) by groups of individuals for special purposes."

A typical BEACONet frame looks like this:

W2EV>HY1G02-15:[FN03XD] w2ev@arrl.net
^^^^^^ ^^

|

This makes the frame look like an ALTNET to APRS software.

So...BEACONet stands as it originally was...an application of UI-Frame technology that:

- * can use APRS(tm) software (but doesn't have to)
- * operates within the APRS(tm) spec as an ALTNET
- * allows for experimentation and expansion on that spec without destroying it

If you think of APRS(tm) as being "Major League Baseball", then think of BEACONet as being "the farm club". Just don't go "calling up" any of the stuff we're developing without being prepared to trade us back enough to make it worth our while. :o)

Back to having fun...ya know...the eta-Aquarids meteor shower is just around the corner...and the spring/summer Tropo season is forming; anyone want to actually generate some RF? :o)

With a smile and a wink,
Ev Tupis, W2EV

According to the APRS Protocol Specification:
(pg 23/128): "In all of these cases, the Destination Address SSID may
specify a generic APRS digipeater path."

(pg 25&26/128): A chart describing the "Generic Digipeating" noted
above.

Yet, when I launch a frame which includes this information, it is
ignored by all of the APRS digi's around me (even though I'm LOS to at
least three WIDEn-N digis).

My APRS frame looks like this:

W2AAA-2>APW248-3:=4310.21N/0 . . .

^

This infers WIDE3-3 from the protocol spec

Am I missing something about the use of this function?

Ev, W2EV

Your use of different TOCALLS for everyone in Beaconet is not a fixed string, thus it is not an ALTnet. Thus no Kenwood D7, or D700 user can listen in because the ALTnet which they might set iaw the APRSpec won't match but one user at a time. Thus, you exclude probably 10,000 users from monitoring your Beacon Net while traveling. Such exclusion to save one byte seems awfully drastic. More comments at end...

Yes, but only people who set their ALTnet to "HY1G02" will see it. If any letter changes, then it is a different ALTnet and will not be decoded by anyone operating IAW the Spec.

Yes, someone can set thier ALTnet to HY1G02, but he will only receive packets from that station only. Not anyone else in Beacon net unless

the station is identical in Power, Antenna, HAAT, Direction and Gain.

But there is no way for an ALTnet compliant APRS station to receive a packet from any other combination, without changing their entry.. Or disabling ALTnets entirely.

Bob

This SSID DIGipeating feature was put in the Spec for the next generation of APRS (so that everything would be backward compatible when we moved to APRS Phase III.

It allows HOPS of up to 7 HOPS using the WideN-N protocol, but saves 7 bytes per packet by eliminating the DIGI field entirely... and only using the SSID as the number of hops.

I think only DIGIned and UIdigi and the other new digi codes support it yet. The Kenwood D700 digi mode also does... (hummmh, I forget. Ill have to look up how to do this)... Bob

Gotcha. That explains why no one processed it. What's the plan for this feature? One would think that it ought to be supported by stand-alone digi's if it's going to be effective. Is there a movement afoot to get TNC firmware to support it?

Ev:

Yes, at least according to what I saw on here, 12 people had volunteered. However, it appears volunteers were not what was required (even though the old WG had requested them.... go figure?). Two people (outside of these volunteers) were asked to join the WG, and they both declined. Hence the spots still remain open and no direction or next step (at least published) has been set. So your guess is as good as mine.

It has been said, that if you do something, and submit it to the WG (this list?) some action will be taken. It has not been my personal experience this is the case, hence my feelings they had ceased to exist as a viable body. Granted, my contribution had been minor, but I am reluctant to make major contributions (to a spec document) with no feedback or in a vacuum, as had been suggested the current mechanism is. I suspect lacking such direction or feedback, the previous statement would apply to others as well.

My impression here is to just do what you want.... if you get sufficient user support it will be adopted via assimilation. A spec document is not a spec document without a compliance mechanism. So, your best bet here is just to get some user support for your BEACONNet extension, and write your own spec. Approach some of the authors requesting support for it (most seem more than happy to do this) and have at it. As to the entrenched incumbents such as Kenwood, I suspect if you get sufficient interest, they will adopt it. Not sure if BeaconNet is compatible with DX Clusters, but if not, you might consider this. The DX'ers, as a group, are not afraid to spend money. This is a language Kenwood understands.

Good luck

Jeff

SO far we have only seen Digined and UIdigi and maybe some others? No, no big movement. For a closed net where someone has hundreds of mobiles and only a few digis, it really shortens packets and allows more users.

In trying to find an APRS compliant protocol to do all the BeaconNet needs while still being SPEC compliant (and receivable on a Kenwood), I came up with this:

W2EV-xx>CQxxxx,HOP2-2:>GG##ggXX.....

It gives at least 7 bytes worth of special BEACONet information and the total cost is only ONE (1) more byte than the existing BeaconNet format. Here is how:

* FROM call SSID for one byte (1 of 16) or 2 bytes (1 of 10 & 1 of 5)

- * In the T0call, you can use 4 bytes (1 of 36 each)
- * In the GRID square report, you get 2 bytes
 - The first one (the TABLE or OVERLAY character can be 1 of 36
 - The second one (the ICON) can be one of about 90

These 7 or 8 bytes can convey a lot of info...

This is the preferred Gridsquare report format as written in the spec.

So I think that this format would give you a very powerful format for BEACONet packets that could be received by anyone, this includes:

- 1) Newbees who have no clue how APRS or anything else works, but if they tune to BEAOCNnet, they will see something without having to know "how" to set up their APRS software...
- 2) Kenwood mobile operators (remember the D700 tunes 6m, 2m, 220, 440, 900 and 1296 bands)...
- 3) Kenwood backpackers and QRP operators with only their HT's...

Although it would be nice to use ICONs that are meaningful, I don't care at all if you use any of the 90 icon symbols to mean anything you want in BEACONet. That is the kind of flexibility that APRS should be able to afford... And there are some un-used ICON definitions that we could possibly consider if you find that defining one or two more might make things really neat...

And the OVERLAY characters can be applied to ANY ICON, so it can be considered as a completely independent byte... again, though, it would be nice if it made visual sense in most cases...

Anyway, just an idea to let you get lots of info in a standardized way, into the shortest packet and still be receivable on all APRS stations.

Wait wait. Please don't draw conclusions prematurely by inferring that a one byte space-saving is the sole reason behind the desire for BEACONet frames to be treated as an ALTNET. That is not correct. There are *many* reasons for doing so (I'll address them in a future eMail if this is a point that needs clarifying). Let's take one thing at a time.

Your reply hit the following topics:

- * Kenwood D7 and D700 don't have the ability to disable ALTNET filtering and therefore would be blind to this variation of the BEACONet protocol
- * A BEACONet T0-Call of "HY1G02-15" is a specific ALTNET unto itself and you said, "... only people who set their ALTnet to "HY1G02" will see it. If any letter changes, then it is a different ALTnet and will not be decoded by anyone operating IAW the Spec."

The flippant response to the second item would be "gee...you built-in the ability to turn off ALTNET filtering into APRSdos, why didn't you tell Kenwood to do the same thing?" :o) <-really intended as humor, not a flame...it's really nice that the filter-off function is in APRSdos.

- you know that APRSdos *will* decode BEACONet by turning off filters, and so will UI-View (natively, without the need to mess with anything). WinAPRS won't . . . but that's because it doesn't appear to follow the ALTNET spec at all...period.
- since the BEACONet T0-Call information appears to work on two major APRS software titles, the discussion turns to the Kenwoods

```

*** The rest of this includes interests of the BEACONet community ***
*** and is a bit lengthy. Please read it to get a better insight ***

```

As for the D7 and D700 implementation... this is a variation of a larger issue: how much "backward compatibility" does one offer when developing new systems? This is a tough one to put one's arms around...especially when the "old stuff" is still being actively marketed. There is a fine line between a manageable leap in technology and an unmanagable one (one wonders if OS/2 would have been more successful, had IBM sat on it until now -- but I digress). :-)

This is the same issue that had to be delt with when determining just how important it was to use **only** TRACEn-N digipeating (exclusively) in the BEACONet service. That would mean that only Kantronics KPC-model TNC's with ROM 8.2 or above could be used for stand-alone digi's (though I've been told that the new UIDIGI firmware may support it now).

Given that tracing RF paths is a core BEACONet need, the decision was made to do just that. We couldn't take the risk of someone putting a non-call substituting, channel-flooding alias on the frequency (imagine even an inadvertant WIDE,WIDE,WIDE in a world-wide collision domain...ouch!).

So...back to the limitations of the D7 and D700. If BEACONet-ers used the (very valid) variation of the protocol that started with CQ, instead of HY, I'm hearing that they would be able to decode the packet correctly (even though [GR##ID] is marked as obsolete in the spec)?

Then the question becomes...how important is "HY" to a BEACONet frame (W2EV>HY1G02-15:[FN03XD] w2ev@arrl.net)? HY is a frequency designator. H=HF (3-30 MHz) and Y=the 26th segment from 3-MHz (the scale runs 0,A,B,C,D,...Z) which is 28-MHz -- in this case. Launching a BEACONet frame as CQ1G02-15 is fully allowed in the APRS spec (and allowed in the BEACONet spec), but there would be a loss of "band-of-origination" information.

Here is the thought-tree on this topic:

* The long range hope is that BEACONet will take on a following

of it's own with an audience that may not necessarily be APRSers today (DXers and testers)

- * It would be advantageous to establish an APRServ-like Internet service in the near future (maybe AHost?)
- * There is no frequency-of-origination flag in the APRS protocol specification and no way to separate frames by frequency once they are collected by APRServ...so all frames go on the same map
- * A screen full of icons on a map means very little to the BEACONet service if band-information can't be parsed out (hmmm...which band is responsible for the propagation? <smile>)

At this stage of BEACONet experimentation...I'd say that the answer is "yes", it *is* important to embed frequency in *every* transmission; even if that leaves "10,000" D7/D700 users out of the loop for decoding the transmissions of others. They bought their transceivers for APRS...which is where they will continue to work.

Given that the TO-FIELD goes out with 7-bytes consumed whether you use them all or only "CQ" (that's the AX.25 spec), putting it there seems to make a ton of sense.

Of course, this all may change by the time this BEACONet stuff either matures or fizzles out entirely.

Well, I've started and stopped this eMail several times and it's now midnight. I hope it didn't come through as too choppy. I'm going to bed. The twins wake up at 7 without regard as to how late I stay up. :o)) Thanks to anyone who decided to take the time to read through this eMail and understand the interests being addressed.

Ev

>
> W2EV-xx>CQxxxx,HOP2-2:>GG#/#ggXX.....

((by the way, before I Bob's email in full perspective ... neither "band of origination" nor "antenna pointing vector" information appears to be contained in the suggestion above...so it hardly begins to meet "all the BeacoNet needs"))

Bob is sharing a note with the listserve that he shared with me privately last week -- and I replied to. I'm saddened that he did so, as I'd have preferred to not air this topic to the list. Unfortunately, the note can't go unreplied to.

My reply to him included "human engineering" issues that included *two* times during the development of BEACONet in which I attempted to keep up with a spec that changed just as I reached a publication deadline and the discouragement that it engendered.

- "Space Mode" used to exist in APRS-dom. When invoked, the grid was placed in the To-Field to save transmission time (hmmm...the same reasons for BEACONet's wanting to do it that way).

Just as I was going to roll this out for PropNET (as BEACONet was called back then)...the spec changed to antiquate it in favor of [GG#/#gg] in the comment field.

- I quickly re-wrote the article that I was working on (QST of November 1999) and resubmitted it for publication. This was no small task...as anyone who has ever written an article

knows...and inadvertantly left out a very important item that proved to be devastating (FULLDUP ON for for Meteor Mode in a manually-configured WinAPRS Leonids station) as a result of the rush to rewrite. Bob later wrote to the listserve something about "maybe next time the meteor effort could be better done".
arghhhhhhh!

Discouraged from the work that had to be redone, I took some time to "regroup" around the new concept of [GG##gg] and continued developing.

- [GG##gg] is no longer in favor, but it is now >GG##ggxxx....
Oh...my...gawd! Guess what? Watch out for May's QST...it's already gone to press. (I'm leaving out a lot of detail of my conversation with him and the wg around getting them to *not* abandon [GG##gg], by the way)

I've done my best to follow this APRS moving target, but at some point I've got to say "enough is enough". BEACONet is a cousin to the APRS service. The APRS spec shows [GG##gg] as obsolete, and the BEACONet service has adopted it. Get over it for now and move on.

If the APRS service wants BEACONet to be fully compliant, then someone is going to have to work to address the issues of the BEACONet service -- as a user of the BEACONet service...not through the eyes of the APRS service as the two services have different needs.

Until then, authors of software that decodes UI-frame packets are encouraged to build-in BEACONet parsing of To-Field information and reap the rewards of marketing to a whole new group of UI-Frame packet users to which the APRS service does not cater.

Evhen Tupis, W2EV

I'm going to bed...maybe the morning light will melt the grumpies away.
:o)

I have shown how you can fit all of the same data in a fully APRS spec compliant packet and it only takes one more byte, so the conclusion seems inescapable?

> - since the BEACONet T0-Call information appears to work on two

Yes, two out of say a dozen?

> *** In a nutshell the text below will discuss: ***
> *** + The dilemma of "backwards compatibility" ***

I see no reason why it must be in the T0field and make the packet non-APRS compliant when there are other places to put it.

> For the D7 and D700... how much "backward compatibility" do [we need?]
> If BEACONet.. started with CQ, instead of HY,... they would be able to

put it in one of the other 8 "free" bytes I pointed out in my proposed solution. There are all kinds of places to put it...

> * There is no frequency-of-origination flag in the APRS protocol

Each packet has as many free bytes as you want. One can put anything in any of the free bytes in any APRS packet. Anyone can decode them to mean anything they want... without violating the spec. I am all for adding such a designation for this application, but just not in a place that makes the packets non-compliant.

> * A screen full of icons on a map means very little to the BEACONet
> service if band-information can't be parsed out (hmmm...which band

The BAND information and sub-band information should go in the ICON and OVERLAY characters. Then a quick glance at any BEACONnet map would instantly convey that information. Here's how:

Choose as many ICONS as you need for all of the bands (there are 90). Then use the 36 overlay characters for the sub-band. Any author then that supports BeeacoNET would parse out BAND and FREQ info from those bytes and do anything you want with them. The ICONS don't have to make sense. It's just that those bytes are "free" to use for conveying this information.

* At this stage of BEACONet experimentation...I'd say that the answer is
* "yes", it *is* important to embed frequency in *every* transmission;

And I agree 200%. Just don't put it in a place where it violates the spec and makes BEACONet non-compliant with APRS and locks out thousands of users.

Huh? There are 8 bytes you can do anything with! and I listed them.
in my original proposal:

xx in the FROM call
xxxx in the TOCALL
XX in the Grid format. <== This is where I would put FRQ/BAND info

> Bob is sharing a note with the listserve that he shared with me
> privately last week -- and I replied to. I'm saddened that he did so,
> as I'd have preferred to not air this topic to the list....

I thought we brought this to the APRSspec list for open discussion?
It was a message I sent to you. Not one you sent to me. So I don't think
it is any violation of etiquette to re-post my suggested format here...

Ev, you seem to think I am working against you. Far from it. I LOVE the
BeaconNet concept and am more than willing to do anything I can to make it
popular and a great service. To that end, I am trying to help make sure

it is decodable by everyone, not just the few people who go out and get special software...

You mentioned the QST article as the main reason why you dont want to change. Yet only 2 authors currently support BeaconNET (and I am one of them). This raises some interesting points if you did change to an APRS compliant format at some time in the future:

- 1) Both those authors would release a new version overnight. End of problem.
- 2) ALL other existing APRS software would instantly be BEACOnet capable... End of problem.
- 3) All Kenwood mobiles would be able to monitor BeacoNET anytime, anywhere... End of problem.

Bob

ok...I'll explain it again...

If one is truly interested in finding a good solution to your dilemma, then one will need to take the time to understand the broader BEACONet interests and address them too. As with any system, items become interrelated. One cannot simply offer a solution to one item and walk away, as it may introduce other problems elsewhere. That is the case here.

An additional related item is described here:

<http://go.to/BEACONet> | Information | Contest and RadioSport Use

As one reads over the information, key-in on the last item in the information chart. BEACONet enjoys an alias called RFONLY (although it isn't expressed within that text...the concept is). It is an explicit instruction to not IGate (remember...it's *not* about privacy). UI-View processes the alias correctly and APRSdos doesn't IGate (yet another reason why both of these titles are supported in the BEACONet world).

By taking BEACONet out of the world of the ALTNET something else happens:

- * RFONLY becomes an issue because now all other APRS programs can decode it a BEACONet frame...and they don't recognize the RFONLY alias

The astute observer will have two comments:

- "No one can guarantee that some third party won't IGate a signal anyway, even with the alias"

- "It's not the testers' fault if someone else relays the information"

As for the first statement...while that is true, the chances of it happening are _significantly_ reduced by using a system that is primarily supported by products that behave as needed (an analogy would be the fact that I can write software to digipeat a frame, even if it

does not contain a digipeat alias...but no one does).

As for the second statement...Dan Henderson (Contest Manager at the ARRL) has come right out and said "the use of packet is prohibited" (exact quote) in ARRL VHF contests. It took _considerable_ effort to educate him that DXCluster Spots are different than is simplex, non-digipeated UI-Frame packet. Even then, I'm not sure he truly got it. I'm not willing to introduce other software that ignores RFONLY, given that history.

So...back to my original statement:

> > Please don't draw conclusions that a one byte space-saving is
> > the sole reason behind the desire for BEACONet frames to be
> > treated as an ALTNET.

Here's another. Help us to find a win-win solution.

By the way...I'm subscribed to the list...there's no need to cc: the thread to me directly, too.

Ev

```

The "XX" in the GRID format above is for ICON and OVERLAY character. I would assign your FREQ BANDS to ICONS as shown below, and then use the 36 overlay characters for your frequency sub band information...

BANDS	FREQS	ICON
----	-----	-----
X	3-30 KHz	The diamond
L	30-300Khz	The Lighthouse
M	.3-3 MHz	The tall Radio Antenna
H	3-30 MHz	The existing HF ICON
V	30-300MHz	A VHF Icon (Ill find one)
U	.3-3 GHz	The existing QTH with a Beam
S	3-30 GHz	The existing dish antenna
E	30-300THz	The alternate "E" Icon.

Then not only do your packets contain this detailed info, but they also visually convey this information at a glance...

You could put the Beam Heading in the SSID. or add one character. (The "Z" I added above)

But if you reserved the TO_CALL SSID for SSID routing, then you could actually shorten ALL BeaconNET packets by 7 bytes! You would be eliminating the "HOP2-2" bytes entirely (saving 7 bytes) and then use the SSID (-2) as originally intended for routing. The disadvantage of this is that the KPC-3 does not support SSID routing yet, but Uiview does (or could).

That is why I hate to mess up SSID routing which you could use in the future to great advantage by using the SSID now just to save one byte. So I would probably suggest that you add one character for beam direction. (With the potential of saving 6 in the future)...

bob

> > - since the BEACONet TO-Call information appears to work on two
> > major APRS software titles, the discussion turns to the Kenwoods
>
> Yes, two out of say a dozen?

The interest was to find a software title that would run on most
people's computers, that would meet the interests of the BEACONet
community. These two titles will take care of 90% of the worlds
computers (DOS and Windows). I'm not sure of your point...but the
interest is being met.

The next point that you made keyed back in on the use of the "HY"
frequency designator, rather than "CQ". First...let me say that I'm
giving some serious thought to that...given the potential of embedding
the frequency into the icon overlay (I've got more exploration to do,

though). But another statement makes me think that you are still overlooking another BEACONet interest:

```
> > * There is no frequency-of-origination flag in the APRS protocol
>
> Each packet has as many free bytes as you want. One can put
> anything in any of the free bytes in any APRS packet. Anyone
> can decode them to mean anything they want... without violating
> the spec. I am all for adding such a designation for this
> application, but just not in a place that makes the packets
> non-compliant.
```

There is a BEACONet interest in assuring the shortest human-readable frame. If you are inferring that there are 256 "free bytes" to choose from, then you are missing the point.

In fact...the *only* "free bytes" that exist in an AX.25 packet frame are the ones in the To-Field and any unused bytes in path aliases. All others consume space. The *only* "free bytes" in a BEACONet comment field are the "[]" around the grid...and we included them only because APRSdos requires the "["! (see...there can be concessions <smile>).

Have I missed something?

Ev

Actually, I didn't mean to infer any violation of etiquette...no offense was taken. I intended to simply say "we've already talked about this issue and it has been taken into consideration (for further research)...why is it out there again?"...It's probably simply a difference of style, nothing more.

I also hope that others don't think this is an adversarial <sp?> thing. Nothing could be further from the truth. I'm committed to the BEACONet thing, and am indebted to others for their work and to you for your interest in it.

I'm simply making sure that the interests of the BEACONet community are addressed in any future modifications, if they are made...that's all.

I'm going to parrot back what I understand about your suggestion:

> W2EV-xx>CQxxxx,HOP2-2:>GG##ggXX.Z

W2EV-##>CQnpah,HOP2-2:>GG##ggIO.V

```

||      ||||      |||||
||      ||||      |||||+-- Beam Vector--+
||      ||||      |||||+-- what's this?+--2-bytes for V maybe?
||      ||||      |||||+--- Overlay for the icon (27 needed)
||      ||||      |||||+---- Icon (8 needed)
||      ||||      ++++++----- 6-character grid
||      |||+-- H.A.A.T.
||      ||+--- Antenna Contribution (element count or dBd)
||      |+---- Power Output (1mW to 32MW)
||      +----- Network Personality (Digi, Bridge, Gate, etc)
++----- SSID to allow for multiple occurrences of same call
```

Now...to be clear...your suggestion wastes three bytes entirely:
CQ conveys nothing of use to BEACONet
TO-Call -SSID goes unused...but is still transmitted as a byte.

I like the icon idea, but there is another interest being driven here, too. Because BEACONet is a "network sniffer for UI networks" it is just as important to know the network personality visually, as it is to know the band of origination. Since "n" exists in the BEACONet protocol, it was hoped to use that as the driver for the Icon, rather than frequency of operation. I'm going to play with the icon idea a bit to see what I get (there may be another variation to the theme that could work).

In case anyone cares..."n" is described in the BEACONet protocol specification on the website: [http://go.to/BEACONet | Information | Protocol](http://go.to/BEACONet%20Information).

Other issues still remain. I've spelled them out in other eMails and would be interested in your thoughts on addressing them as part of the package.

By the way...SSID routing is useless to BEACONet...WIDEn-N doesn't allow the tracing that we really need. There is no advantage to is...it will always be a wasted byte.

```

This is a good point. But I am a little confused.

If the non-standard ALNET construct allows you to be isolated from any other inadvertant APRS software from IGATING your packets, then that would seem to be sufficient in itself to solve the problem of RFONLY routing. So why then is the RFONLY alias needed? (I do think RFONLY alias is also a very good idea too.)

Does this mean that all BEACONet packets have the RFONLY alias in them at the cost of 7 bytes per packet?

You do have a very valid point about not wanting conventional APRS software in use by a non-fully-understanding user to link your BEACONet packets worldwide back to RF... Lemme think about that some.... I'd like to find a single bit somewhere that can do that much more efficiently...

Lemme think about this...

bob

RFOONLY is invoked only by stations that are engaged in VHF Contests.
Otherwise, "24/7" BEACONet stations may launch frames with either HOPn-N
or nothing. RFOONLY is an option to satisfy the needs of the
Contesting/DX Chasing BEACONet community, not a requirement for all
BEACONet-ers.

Hummh... conversly, I am beginning to see it as a neat future
for BEACONet. Here is how:

- 1) Using -n instead of HOPn-N saves 7 bytes in every single packet
- 2) This does not need to be a WIDEn-N implementatin. On BEACONet, you can define that all such -n packets will be digipeated as TRACEn so that they include their path.
- 3) Since UIview uses KISS mode, ROger could code this into UIview overnight. Also, since the UIDIGI firmware also supports SSID routing, I am sure that its author would be happy to also make this possible. UI-DIGI roms will fit in any of the millions of old TAPR-2 CLONES. Also, any old 286 PC with any TNC and DIGI-NED software also supports SSID routing...
- 4) We can also include the RFONLY flag in a single bit. Here's how:

SSID ROUTING FOR BEACON NET:

```
if SSID is 0 then no digipeating
if SSID is 1 to N then digipeat and add digipeaters MYCALL (TRACEn)
```

if SSID is 10 to 1N then subtract 10 and digipeat as above
but consider this packet as an RFONLY packet.

Thus BEACONet can save 7 bytes in every packet,
It retains an RFONLY flag
It retains a TRACEn-N mechanism
It LEADS the APRS community in using this valuable routing method
It will allow TAPR-2 CLONE TNC's using UI-DIGI firmware to be used
for beacon net without the expense of KPC-3's for everyone...

This would be a long term goal. It sort of depends on how many Beaconnet users use KPC-3's, how many use TAPR-2 clones, and how many use UIVIEW? I admit it would be a transition, but until the transition was complete, then HOPn-N could continue to be used... and still be compatible.

Actually it saves 14 bytes if you consider that you no longer need the RFONLY alias either...

Bob

But Bob...the APRS Protocol Specification (page 26 of 128) expressly
says that ToCall SSID routing is WIDEn-N and WIDE. You're not proposing
that BEACONet deliberately tool-up in opposition to the spec, are you?
;-)

Chuckling just a little,
Ev

I thought you might noctice that. But the difference is that these packets are still decodable by everyone. This modification to what is in the spec is a non-exclusive "enhancement". In ANY WIDEn-N digi, it has alwasys been a SYSOP prerogative to enable path tracing in a closed net if he likes...

FYI, AFILTER and I believe UI-View both support "NOGATE" already which effectively does the same thing. (keeps the RF gateway from sending the frame on to the internet).

Interesting. Ev was acused of developing BEACONet protocols without open public discussion of the protocol and thus it evolved as non APRS compatible. He brought it here to have a public discussion of how BEACONet can or cannot fit into the APRS protocol. I thought that was what this list was for?

Just hit DEL key if you are disinterested...

Bob

(from Garmin's website - and verified by numerous other sources)
Q. How is the checksum calculated in NMEA 0183?

A. The checksum is the 8-bit exclusive OR (no start or stop bits) of all characters in the sentence, including the "," delimiters, between -- but not including -- the "\$" and "*" delimiters.

The hexadecimal value of the most significant and least significant 4 bits of the result are converted to two ASCII characters (0-9, A-F) for transmission. The most significant character is transmitted first

> Just hit DEL key if you are disinterested...

* The BEACONet protocol was opened to public scrutiny on TAPR's
PropNET/BEACONet listserve. It was also discussed with Bob B.
during development. It has never been "without open public

discussion". Check the list archives. The topic is there.

- * Since the "Cause" is inaccurate, how can the "effect" of "thus it evolved as non APRS compatible" be defended? Never the less, it was said ...
 - From an APRS perspective (which is what this seems to be), the BEACONet system operates as an ALTNET (to the letter of the APRS protocol spec). Ok...so maybe it's a *bunch* of ALTNET's, but it *is* fully compliant with the spec on ALTNETs.
- * I brought the discussion here because I wanted to clear the general APRS listserve of it (it had nothing to do with general APRS). I never said that it was here to see how it "can or cannot fit into the APRS protocol".

Now...for a recap of the thread up to this point...this discussion was engaged because Kenwood radios don't have a function to disable ALTNET filters...therefore BEACONet was proclaimed by Bob as "non APRS compatible".

A secondary discussion ensued as to how to reformat the BEACONet frame to allow Kenwood to decode them...but then the tables turned. Bob found out that APRS(tm) protocols, network topologies and procedures were not BEACONet(tm) compatible (I *hate* when that happens). :o)

Bob's giving this further thought.

I think that pretty much sums it up so far. :o) This thread can continue on or off list...it makes no nevermind to me. I'm learning some good things to *maybe* incorporate in the next revision of the BEACONet protocol spec and lurking folks are being given an insight into APRS's cousin that they may not have previously had.

And again for the record...there is no personal affront intended by me nor taken by me with any of this discussion. The BEACONet concept was based on experimentation...that's what we're doing. A year from now, the experiment may be over and all that may be left is my satisfaction of "doing" rather than "dreaming"...then again... :o))

Ev

> WIDEn-N digi, it has always been a SYSOP prerogative to enable
> path tracing in a closed net if he likes...

I've searched the APRS Protocol Specification on the key words of
"exclusive", "enhance" and "modification" and come up dry. Where can I
get more information on the topic of "modifications that are allowed
because they are considered non-exclusive enhancements"?

Recap: Jeff Brenton suggested that we look at a way to create objects that expire. This week's rash of springtime storms underscored a serious need for self-deleting objects to automatically clear the display of obsolete, superseded or otherwise out-of-date objects.

The proposed protocol consists of adding a expiration time to the comments field, like so:

```
;CELL1 *092345z4903.50N\07201.75W[088/036/EXP=0090
```

This, of course, says that the CELL1 wall cloud object moving east at 36 Knots expires 90 minutes after 2345z on the 9th. Field is in minutes and must have all four digits; "9999" minutes is 81 minutes shy of one week, so this gives us a good practical range.

The user interface default value should be relatively short - 30 to 60 minutes is a good start for discussion. There is no default in the on-air packet - the value is always specific. "/EXP=0000" is immediate expiration and is illegal; an object with no expiration should not have the /EXP= parameter.

This has maximum backwards compatibility (i.e., doesn't break anything) and is human-readable when it isn't supported by the receiving program.

By expressing the time as a time-out value rather than an end time

means a lot less work for the parser. We've already parsed the 092345z, so the expire day and time is simply 092345z + 90 minutes.

What we need now is to hear from anyone who might think of a compatibility problem we haven't seen yet so we can get hopefully get quick agreement to "just do it".

Is it necessary to have "/EXP="? I don't believe anything else uses 4 zeros "0000" so you may be able to tack it on the back 088/036/0000 of the report. It appears the other extensions use 3 zeros "000" at this location i.e. bearing/number/range/quality. Check for a "0" instead of a "/".

On the other hand "/EXP=" is pretty easy to search for.

What about "/E=" which is similar in format to the "/A=" parameter for altitude?

Rich - Wn0x

And two fewer characters liable to corruption. (And you don't really need the "=" either).

The shorter the packet the better.

I think it's a good solution, but why not using
/D=1234 for duration 1234 minutes, or
/X=1234 for expires in 1234 minutes

It's a little bit shorter...

Rolf

Bill:

I'm copying this to APRSSPEC as well since some of the APRS authors there are already discussing it.

I believe Bob's algorithm was based on picking a second of the minute to beacon on. It was seeded with your callsign. He would have posted it a few weeks before Dayton, not sure if it was last year or the year before. This required no changes to anyones software, it just required you to set the clock on your computer or sending device.

Coordinated time slots would be best as you suggested, but it requires a internet connection. We actually discussed this before.... the way you solve it is to have two granulates for the devices beaconing. You can pack the devices on the internet second by second where as the mobile devices you assign in a different segment (as far away (in time) as possible).

Basically, the mobile devices could send in the last 30 seconds of the minute, where as the internet connected devices could send in the first 30 seconds. You'll still have some collisions (as it is only a 50/50 chance the mobile will have his time set

correctly to hit that last 30 seconds) but at least it will help somewhat.

Also, what will help alot is to STOP beaconing the first time you see your packet repeated. You could calculate sat rise and sat set, and only beacon until you are heard during each interval. A server could handle this as well.

Wouldn't that infer one-minute beaconing through the ISS? I was under the impression that folks were attempting to avoid that if possible.

No. Second of the chosen minute. Could be once a minute,
or once every 10 minutes. Lacking a centralized slot server, you need a
universal random method to chose the second of the minute to send on as
well as beacon frequency, whatever it might be for ISS.

In any case, I'm not telling anyone how to do anything. Don't have any
interest myself in beaconing through ISS. Just recalling a
similar discussion regarding beaconing at Dayton which also dealt with
hidden terminals.

How is this different, in a practical sense, from just turning on a
transmitter with a fixed beacon rate, at some arbitrary time?

What happens if I'm sharing a "slot" with an alligator?

It is no different. Yet explain to me, lacking any formal specification, how you would insure that this is indeed arbitrary? Humans are not random, and the point of the posting I referenced to was some human pseudo code for insuring this randomness. I believe the callsign was used as the random seed (for the slot that the beacon occurred in) and some beacon rate was pre-agreed upon.

The point here, is that if you assume humans are random, when it comes to numbers, you'll end up with bunching. They are not random.

> What happens if I'm sharing a "slot" with an alligator?

I begin to wonder when someone asks a question they already know the answer to, in particular when they are not an attorney. Of course it won't work if someone decides to ignore the rules of the road. If you think what I was suggesting won't work, just say that. It won't hurt my feelings in particular since it wasn't even my idea (although I do agree it is a good idea, your pessimism may be closer to reality).

My only reason for posting was to mention Bob B. had came up with a pseudo algorithm some years back for the Dayton Hamfest. It *might* apply here. Because the search engine on the TAPR Lyris site is broken, I was unable to post a link to the message.

-Jeff

Another answer might have been that sharing a slot with an aligator is not that bad. Even if he has 10 dB more power (500 to your 50w) then at many times through the pass due to all the other variables going on, sooner or later, you are going to be 10 dB stronger and he is going to be 10 dB worse. Bingo, you get in...

Algorithms aren't random either.
The best you can approach is "difficult to predict", and "evenly
distributed".

I was wondering if anyone had implemented/suggested a method to handle that.

No, they are not. That is why you need to chose a seed number that is random.
Maybe use the checksum of your callsign as the seed number (or some combination
of the unique letters in your callsign).

> The best you can approach is "difficult to predict", and "evenly

EXACTLY. Evenly distributed is the key here. Still no where near as good
as some sort of assigned slotting system, yet better than the bunching and
anarchy when folks are left to their own choices.

> > > What happens if I'm sharing a "slot" with an alligator?

The FCC rules define that fairly well. Minimum power needed for communications.
I would think into a pair of crossed dipoles, 5 watts would be plenty.

It is really hard to enforce morality. If someone runs 500 watts (20db more than
is needed) then all they care about is themselves. I don't have a solution for
that one other than to decline to participate in a RF power war, if that is what
it
is becoming. Anyways, ISS is long term so the congestion will clear out in due
time
after the novelty factor wears out. Then some useful applications can be deployed.

What I don't understand in this discussion is why anyone thinks that bunching of transmissions will occur in the current situation, because surely anarchy is inherently random? Could someone explain to me the mechanism that is going to cause the bunching?

As far as I can see, the only advantage of assigned slots would be that if you say to someone, for example, "transmit on second 37", then you're also telling them to transmit no more than once a minute.

Also, I'm not so sure that the long periods of silence from ISS are as a result of it being held off by uplink traffic. If it was, then I would expect to see it spew out a whole bunch of frames when eventually it got in, but I haven't seen any evidence of that at all. What I do notice is that it seems much easier to access it when it's at a very low elevation than when it's at a high angle, and that certainly isn't because of the antennas I'm using. Could this be as a result of the position of the 2m antenna on ISS?

I'll try.

Every so called "random number" algorithm, at least the ones I have worked with in computers, really isn't random. You need a seed number to at least give it the chance of being random. Bob had suggested the seed number, in his post some time ago, as being the persons callsign or some combination.

You also need a standard algorithm to plug that random seed number into, be it a computer algorithm or human pseudo code. The "algorithm" in this case could define power levels, when to beacon, when a beacon is successful, how often to beacon, ect. The random element in the last paragraph is to insure even distribution of the transmissions.

Bunching is a known human behavior. One can see it in many forms.... the desire to pick a "round" number, working 9-5, rush hour, bidding on auctions, waiting until ISS is about to rise above the horizon to turn the beacon on. Doesn't matter the reason, it is just human behavior when most of us are left to our own means or lacking any pseudo code (etiquette) to guide us.

Anarchy is NOT random although in its earliest stages it may appear that way. Anarchy means the lack of any central control or group cooperation. However, anarchy is not a stable system. As a behavior system, be it human or political, it has a very short half life. As it progresses, its behavior becomes less and less random as it moves towards a organized system. In the political arena, we have periods of anarchy, however they typically don't last long. Local chieftains gain power over the local population due to some power they might have a monopoly on. Soon after that, further consolidation occurs. This is born out time and time again in history.

This same behavior model could be transposed to ham radio. Even though most radio regulatory bodies in most countries state to use the minimum power required, sales of HF amplifiers are brisk. The HF DX pile-ups are a good example of local chieftains rising to power. The station with the biggest antenna and biggest amplifier will get the contact. Even though in many cases the station with 10 watts and a dipole easily could make the contact, they are unable to compete against the powerhouse station.

In ISS we could have the same situation. Certain stations could beacon once every 10 seconds. Certain stations could run 500 watts when 5 watts would work. The stations that can afford 500 watt amps and don't see a problem with frequency beacons become the local "chieftain". To compete against the chieftain, you have to raise your power level and/or your beacon rate. Lacking any psedo-code, we have a anarchical system. A true anarchical system is unstable, hence local chieftains will arise.

With some assurance of random distribution, and some rules of the road, access would be more equitable. It also would approach the Aloha model (and with

bunching it is less than aloha). Looking at Dave Vanhorn's example, with the 500 watt station on his 5 watt slot.... you also could dither each slot randomly within a certain window (although that would require software, up until now everything I spoke of didn't).

>As far as I can see, the only advantage of assigned slots would be that
>if you say to someone, for example, "transmit on second 37", then you're
>also telling them to transmit no more than once a minute.

I was primarily discussing means to encourage random distribution as opposed to a coordinated slotting method. This would require cooperation among the authors. However, if such is the case, there are significant advantages to slotted aloha over aloha. I suggest you review some of the texts on packet radio as you will clearly see the advantages, in particular for systems that are comprised primarily of hidden terminals.

But let's take what you said a step further. The "only" advantage you state, one of being able to assign slots and times, into itself is a significant advantage.

But you can take it even further than that. Since this "assignment" is made by a server that has access to all these stations, and their receivers, it can tell the sending station when in fact it has been heard by ISS. Then, it can instruct the sending station... OK, ISS heard you, stop beaconing until ISS is at the other end of the pass. This then opens up the slot for another station.

>Also, I'm not so sure that the long periods of silence from ISS are as a
>result of it being held off by uplink traffic. If it was, then I would
>expect to see it spew out a whole bunch of frames when eventually it got
>in, but I haven't seen any evidence of that at all.

I'd expect it to be operating in "FULLDUP" mode, that is ignoring CSMA. But maybe it is not. Your question is best directed towards the ISS team.

>What I do notice is
>that it seems much easier to access it when it's at a very low elevation
>than when it's at a high angle, and that certainly isn't because of the
>antennas I'm using.

What kind of antennas are you using? Most (all) amateur omni antennas direct most of the signal at the horizon. The best kind of antenna to us for ISS should be crossed dipoles over a screen. This would give you the best signal as it went overhead, whereas an omni would give you the worst signal overhead.

Now in summary, all of my statements regarding packet theory (and the oversights) were known by those that designed the ISS digipeater. Everything could have been addressed before launch. It apparently wasn't. Hence, I don't expect anything

to change. It is primarily a PR tool, and as such, it is targeted exactly right.
The
good news here is the novelty will soon wear off, and possibly we can use it for
some
limited useful things.

I think rehashing Bob's Dayton psedo-code (Bob?) might be useful as it can be used
by
mobiles, but a worldwide slotting system, while a good thing, just wouldn't be
that
useful due to the fact it would not be universally adopted.

Thanks for the interesting reply. Perhaps I should make the point that I was specifically commenting on the concept that "bunching" of transmission is likely to be currently occurring. To expand the concept, what it would mean is that -

At any given moment there are 'n' hams within the footprint of ISS attempting to access it, and some mechanism is causing the transmissions from those 'n' hams to "bunch" in time rather than be evenly distributed.

I'm afraid that I'll remain sceptical about that until someone comes up with a believable "for instance" that could cause it to occur.

>Bunching is a known human behavior. One can see it in many forms.... the
>desire to pick a "round" number, working 9-5, rush hour, bidding on auctions,
>waiting until ISS is about to rise above the horizon to turn the beacon on.

But that varies for each ham in the footprint, because they don't all live in the same place. They also don't all have the same horizon angle, the same antennas, the same receiver sensitivity, accurate clocks, etc, etc.

[snip]

Given that the TNC reset - hence the NOCALL - my assumption is that it's operating half duplex. Perhaps I'm wrong?

Circularly polarised crossed dipoles with reflectors underneath (wx sat style), colinear and a circularly polarised beam. However, I'm not specifically commenting on my own attempts to access the digi, my observations are based very much on what I'm hearing of other stations attempts. (Note - I'm making these comments because I find the subject interesting, I hope no-one regards it as a complaint or criticism!)

It could of course be that the ISS receiver is being totally blocked by in band or out of band traffic. It certainly gives the impression that it is hearing very little. For instance, I've noticed that if a station connects to ISS (NOCALL), and the TNC on ISS gets in a situation where it's polling the connected station, the poll frames will be transmitted every few seconds, which doesn't suggest that it's a simple case of being held off by uplink traffic.

[snip on bunching]

I'm stating bunching is part of human nature. We are not random creatures. While I will concede to you that outside random influences can mitigate the effects of bunching, I don't think we should depend on them nor assume such is the case. Someday everyone's clock may infact be accurate for example. You can't depend on deficiencies to always exist.

In any case, bunching is just one piece of the puzzle. The idea is to have a standard algorithm that everyone can use... be it human pseudo code or some computer program. Doesn't matter. Lacking this, it is in fact anarchy, and the rules of anarchy begin to take affect. CQ contest, CQ contest.

> >What kind of antennas are you using?

And is it safe to say you are in the minority here? Most of the ones commenting on using ISS I have seen are using conventional vertically polarized omni's.

> However, I'm not

> specifically commenting on my own attempts to access the digi, my

Which means your observations are entirely consistent.

Let me ask you this. I was talking with another fellow off SIG and he indicated to me he was observing some deep fading with the ISS station. He was using a 3.5db gain vertical on his car. With your crossed dipoles, where you observing any deep fading? (>20db) I suggested that ISS is using linear polarization as opposed to circular polarization, which is the norm for space coms. In your case, using circular polarization, your fades would be minimal. Is such the case?

Actually, a thought just came to me. Since ISS is receiving and transmitting on different frequencies, there is no need to hold off for anything and it should be in FULLDUP mode.

They don't have duplexers up there, Jeff! There would be considerable
desense of the receiver in doing that, even if they had two antennas.

Pic-E, MIC-E, and HamHUD-III come to mind as APRS end-stations that do not assume the existence of a TNC, and therefore do not accept TNC-style text strings as input.

> By "raw AX.25 frames" I presume you are proposing a new file

I assume that all APRS programs accept 1200 bps AFSK, either baseband (e.g., similar to what you would expect out of an audio jack on your rig) or RF.

> Alternatively, someone must write
> programs to transmit the info on the air (or two TNC's back to back).

I believe that making it easy to create and run tests against APRS software will be a good thing for the APRS community. I believe that it will lead to a much greater number of tests being developed and run. This will lead to a greater understanding of how the different programs respond to various packets and how the programs compare to the APRS specification. It may even lead to an overall improvement in the APRS implementations.

Obviously, the hardware part isn't very hard.

Somewhere, I have a Java class that represents an AX.25 packet. It can create an instance of itself from a TAPR TNC2 or AEA/Timewave text string, (or, in pre-object-oriented language, it can take a text string as input). The class can output itself as a binary string or a TNC2 or AEA/Timewave text string. This class is pretty liberal; it accepts almost anything that is close, even some of the combined TNC2/AEA format packets found on the APRServe data stream.

It wouldn't be too hard for the class to output itself as a KISS string. I will probably do this in the next few weeks for another project.

More importantly, this isn't really hard code. The difficult part is correctly parsing all the variations in TNC strings, particularly if you want to use the APRServe data stream as input. As you mentioned, many APRS programs have this code already (although I suppose the source code for many of these implementation is not freely available).

> If it were a TNC text file, click open and you are testing.
>
> What precisely do you gain by using this format other than being more pure?

First, TAPR TNC2 text strings are not adequately expressive. Some valid APRS packets cannot be encoded using TAPR TNC2 text strings (e.g., may result in non-printing characters which may or may not be preserved). The TNC text format doesn't allow some of the AX.25 fields to be set (e.g., AX.25 reserved bits). I don't think the TAPR TNC2 format allows the AX.25 command/response bit to be controlled, although I think the AEA/Timewave format does.

Second, I believe a language for representing APRS test messages should also be able to create invalid messages. A reasonable example is APRS messages without a terminating CR. I don't believe these can be created using TNC text strings, but I believe that messages of this form used to cause one or more APRS programs to crash.

Third, I believe that anything that continues to promote the TNC model at this point in history is a disservice to the digital amateur community. TNCs were instrumental in the popularization of packet radio. However, that was a very long time ago -- we shouldn't be thinking in terms of an architecture that made sense for C-64s.

Finally, I am trying to answer the question: Ignoring other practical considerations, what would be the most powerful method of representing APRS packets for the purposes of creating test scripts?

I suppose you can call my proposal more precise, more expressive, more correct, more modern, or even more pure.

-tjs

James:

The FULLDUP ON command just tells the TNC to ignore the Data Carrier detect signal. Might be a different command for other TNC's, but that was what my TNC2 was. Doesn't mean you really are full duplex.

-Jeff

Wrong. None of my programs accept AFSK, and in fact for javAPRS and findu
there is no way to connect a TNC directly, so the data would have to come
through another program first. Nor do most of the client programs take
audio directly, requiring a TNC or sound card to convert the AFSK into
text or KISS frames first.

No it isn't hard. However, you seem to be advocating multiple back and
forth conversions before the data actual gets to the program's parser,
which increases the chance for error. KISS!

Setting undefined bits is hardly something that needs to be part of the
testing suite. If someone defines a bit that the AX-25 protocol reserves,
it is simply not a valid AX-25 packet!

Non-printing characters can be present in a text string, in fact they are
all the time. There are only a handful allowed in the spec, and none of
these are ones that even require escaping (normally ctrl-v) like return.

>Second, I believe a language for representing APRS test messages

Most APRS packets are transmitted on the air without a trailing carriage
return. If you want to include one in the string, you must escape it,
e.g. <ctl-v><cr>

>Third, I believe that anything that continues to promote the TNC model

Version 1 of the aprsspec is, and always we be, heavily dependent on the
TNC model. We are talking about the test suite for version 1 of the spec.
If there ever is a version 2, and it is not dependent on the TNC model,
then your argument makes sense.

>Finally, I am trying to answer the question: Ignoring other practical
>considerations, what would be the most powerful method of representing
>APRS packets for the purposes of creating test scripts?

>

One that can be looked at and examined by eye, without the need for
editing software. You didn't address this point of my argument. How
exactly do you plan to create and edit these packets?

As I said, you can use a vanilla binhex editor, but then everyone
writing, editing, and even just looking at them needs to become fluent
with the ins and outs of AX-25. You could write an AX-25 specific editor,
but you'd need at least Mac, Windows, and Linux versions for it to be

available to all who would be interested, and even then some knowledge of the AX-25 spec would be needed.

>I suppose you can call my proposal more precise, more expressive, more
>correct, more modern, or even more pure.

>

No, I wouldn't, I'd say it's more effort-intensive, and more error prone.

.

Once again I have been handed the utterly impossible task of covering all of APRS in 45 minutes within the TAPR Digital Forum on Friday. Without announcement I have already received four requests for time. In previous years, I tried to do a "What's New" sort of presentation myself, but this year I will let people speak for themselves...here are the ground rules:

1. Anyone that wants to talk should email me directly (k4hg@tapr.org) with a request, giving presenter's name, callsign, and topic. The deadline for requests will be 0000z on May 5th. NO EXCEPTIONS!

2. Given that the requests already total more than the allocated 45 minutes, time will be split evenly among all who request. If any presentations run short, there will be a general Q&A period afterwards. NO EXCEPTIONS!

3. Given the problems that usually occur when trying to connect laptops to the projector at presentations, no computers will be allowed. If you have something you want to show off, create a handout to be passed out prior to the presentation. NO EXCEPTIONS!

4. I will be very strict about time, I will notify the speakers in advance of the time per presentation. Time will start from when you are announced, not when you get to the front and start talking, so get there early and sit in front if you want to maximize your time. I suggest you practice to get it all in within your allocated time. NO EXCEPTIONS!

5. No yielding of allocated time (I.e. don't bother getting 5 of your buddies to request time so you can talk longer). NO EXCEPTIONS!

6. If you ask for time, and then can't make it, please let me know as soon as possible so that I can adjust the schedule.

7. It would good to announce where you will be later in the day for questions, since there will be little if any time for questions to be fielded at the time.

Sorry for the rules, but this is hard enough to do in a 6 hour format at the DCC, 45 minutes is really tough.

I'd like a volunteer or two to help distribute handouts so we can minimize disruptions.

Steve K4HG

All APRS Authors:

Brett Lane sent me an announcement that Davis WX will have a new WX station, and he wanted all APRS authors to have a copy of the interface spec. The below message gives a URL for the data...

Enjoy, de Wb4APR, Bob

Do all IGates pass general queries from RF to the Internet? If so, it would make sense to update IGate software to not gate general queries (packets with ? as the first character). This would not affect directed queries, just general queries such as ?APRS?, ?IGATE?, ?WX?, etc. While ?APRS? and ?WX? are rather harmless, ?IGATE? generates directed messages to the originating station. Someone trying to see what IGates are local would get a world-wide response (ugly).

This wouldn't preclude someone physically operating on an IGate from generating a general query to the Internet. It would simply prevent RF originated general queries from creating an overload on the Internet as well as (in the case of ?IGATE?) preventing the Internet from overloading the local RF channel with responses. Brent has modified the latest version of APRS+SA to prevent the gating of general queries from RF to the Internet. I would recommend that other IGate software authors do the same.

By the way, "Why send an ?IGATE? query via RF?" you might ask. "To see what IGates are in range of my station." I would reply.

One other problem observed with general queries. aprsD and others do not respond correctly to ?IGATE?. First, many IGates respond with a message to the query originator. Wrong (see below). Second, text is sent instead of the proper IGATE codes.

This is from the published specification (section 15, para 1):

A station may define a set of one or more attributes of the station, known as Station Capabilities. The station transmits its capabilities in response to an IGATE query (see below), using the < Data Type Identifier. Each capability is a TOKEN or a TOKEN=VALUE pair. More than one capability may be on a line, with each capability separated by a comma.

Currently defined capabilities include:

IGATE,MSG_CNT=n,LOC_CNT=n

where IGATE defines the station as an IGate, MSG_CNT is the number of messages transmitted, and LOC_CNT is the number of "local" stations (those to which the IGate will pass messages in the local RF network).

This means, at minimum, a response to a GENERAL IGATE query is a packet that is solely "<IGATE,MSG_CNT=0,LOC_CNT=1". Additional tokens may be added but that is the minimum (APRS+SA adds FILL_CNT). If the IGATE query is directed, then this can be returned as a message, but never to a general query.

>From my perspective, 2 things need to be done.

1: correct badly behaving IGate software to send the proper response to ?IGATE?.

2: have IGate software filter out general queries from being gated from RF to the Internet.

#1 is the most readily fixable and variations from the standard other than adding tokens should be considered a bug. #2 is an enhancement to IGate software which would substantially decrease network activity.

Hello,

I'm looking for more detail on the area object APRS Data Extension.
The spec (chapter 11, version 1.0.1) gives only a very cursory explanation
of what the area being defined is. I'll list a few specific questions:

Why does it say the size of the areas can go from 60 feet to 100 miles
when the smallest offset (1/100 of a degree) is closer to 1km?

The explanation that the lat/long is the upper left corner of the
object with the other corner being relative to there is fine for
drawing boxes and lines, but gives no guidance on drawing circles,
ellipses, or triangles. The phrase "corner of the object" is left
completely open to interpretation in the cases of circles/ellipses
since they have no corners. Is it a box within which the
circle/ellipse fits? That would be my first assumption, but that is
confused since doing it that way would not have required two object
types since an ellipse inside a square box is a circle.

Triangles are also a mystery. Drawing a triangle from just two points
must be using some unstated rules. What are they?

I think that's all for now.

Thanks in advance for enlightening me on these points.

This one is easy. If you look again at the spec, the size is defined as
the square root of 1/100 degrees, so 1 means the square root of 0.01
degrees, or 0.0001 degrees.

SD> the square root of 1/100 degrees, so 1 means the square root of 0.01
SD> degrees, or 0.0001 degrees.

I'm still confused. The example on page 61 has an offset of one degree.
It multiplies that by 100 to get centi-degrees and then takes the square
root, using that value (10) in the formatted packet. If I do the same
example with .01 degrees, I get the square root of 1, and this is the
smallest number I can put in the formatted packet.
Here are the two equations I would come up with from the spec as I have
read it:

```
packet_format      = (int)sqrt(100 * offset_in_degrees)
offset_in_degrees = (packet_format * packet_format) / 100
```

What equations do you believe to be correct and shouldn't they be put into
the next rev of the spec, mathematical equations being a global standard

for accurately describing the transformation of numbers, etc. ;-)

You take the square root of the decimal number of degrees, not the "centi-degrees" number. If 0.01 degree is your desired number, you take the square root of .01, which is .1, the transmitted number is 10...

I put your "centi-degrees" in quotes, because that isn't the correct nomenclature, the on-the-air-number is the square root of centi-degrees. That you think of it as centi-degrees is the root of your misunderstanding.

OK, so the example is completely wrong. As I said before (and as you can go read in the spec) it says that it has offsets of 1 degree and shows the following:

$yy = xx = \sqrt{100} = 10$

If I have offsets of 1 degree and do it the way you describe in your email I get this:

$yy = xx = 100 * \sqrt{1} = 100$

BTW, this object is slightly too big, right?

The spec also says this:

"yy is the square root of the latitude offset in 1/100ths of a degree."

So basically, the spec has it backwards both in the text (since there is no equation to be found) and in it's example.

>
No, the text is right, if poorly worded:

yy is (the square root of the latitude offset) in 1/100ths of a degree.

rather than:

yy is the square root of (the latitude offset in 1/100ths of a degree).

which is what I think you were reading.

I'd eliminate the "of a degree", as it is technically not correct.

Is Bob and/or Ian listening?

No, I was on a weeks vacation with family and have 900 messages to wade through. But am impressed at your patience in figuring this all out. Id have to go back and re-look at my code. Remember, that what is in the spec is Ian's interpretation and may or may not reflect how I actually did it and then over 2 years got the Sprouls and mine to match up...

Also I have one week to finish our satellite for final review, so wont have time to pick up this ball till later. So thanks for jumping in!

It is painful, I am sure.

One mitigation is that the AREAS initially were up to 400 miles and in about 1995 we changed the scale...to the smaller 100 mile ones... Im not sure if the documentation ever caught up... sorry....

bob

The TAPR offices will be moving a few miles from Denton to Richardson, Texas. We'll be closing on July 26 for the move and re-opening on August 6. The Tucson mailing address will remain the same (it is a maildrop that forwards to the real office address) but the phone numbers will change. Effective August 6, they will be:

Voice: 972-671-TAPR (8277)
FAX: 972-671-8716

The office email address -- tapr@tapr.org -- will not change.

The move is occurring because Dorothy Jones, KA5DWR, our longtime Office Manager, has decided to take a well-earned retirement. It would take a lot of words to fully describe how much Dorothy has done for TAPR, and how much

we've all relied on her over the years, so I'll just say "Thanks!"

Our new office manager is Laura Koster (XYL of Board member John Koster, W9DDD). Laura had a baptism of fire by handling the TAPR booth at the Dayton Hamvention this year, and she did a great job. We're very happy to have her on board, and we're sure that she will carry on Dorothy's goal of providing great service to our members.

73,
John Ackermann N8UR
President, TAPR

Page 64 of the APRS spec talks about weather report format:

"s = sustained one-minute wind speed (in mph).

p = rainfall (in hundredths of an inch) in the last 24 hours.
...
Other parameters that are available on some weather station units include:
L = luminosity (in watts per square meter) 999 and below.
l (lower-case letter "l") = luminosity (in watts per square meter)
1000 and above.
(L is inserted in place of one of the rain values).
s = snowfall (in inches) in the last 24 hours.
= raw rain counter"

Weather Questions:

-
- 1) Why are there two 's' fields defined, wind speed _and_ snow?
Is one a typo and should have been a capital 'S'? Probably snow?
 - 2) Rainfall in last 24 hours. I assume this is intended to be a rolling count going backwards from the current time 24 hours, and not the amount of rain that was seen yesterday. "last 24 hours" implies a rolling count to me. I'm fairly sure on this one, just checking.
 - 3) The "Other parameters" _letters_ are defined, but the number of bytes for each field are not.
I'll assume 'L' has 4 bytes (L999)
'l' has ?? bytes? (l1000, l10000, l1000000000)
's' has ?? bytes? Format? (s1.25, s100.99)
'#' has ?? bytes? Units? Format?
 - 4) What is the "raw rain counter"? Is that the "total rain" counter that some weather stations provide, or the raw counts from the rain bucket over some time period? How many bytes for that field and in what format? 1/100 inch? Inches? Counts?

Here's another one for you:

How do you differentiate "No X" from "No sensor for X".
Is your windspeed 0 because it really is, or because you don't have a sensor?

There are some potholes in this spec.

In the complete WX format, the WIND SPEED does not have a "s" format identifier since it is in a FIXED position. Thus if you see "s", then it is snow.

But then the Sprouls added the format for their verbose positionless Weather format and I think it does have an s...

Yes. I think only the original APRSdos does this. Newer programs took the simpler approach of starting the count at midnight...

It is the current 4 digit count from that instrument. It is useless
unless the receipient is keeping the previous values for comaprison...

Is that defined as "no sensor"?

I see, for ex, weather stations with baro of 0.00.

Seems unlikely to be true, CNN would have been interested.

Windspeed of 0.00, where nearby stations are recording significant winds.
No sensor, Stuck, or ???

Wind direction of 0 where other stations nearby report significantly
different wind direction.

Same questions..

Is this being implemented in the various packages?

A baro of 0.00 would be pretty amazing.

This was one of Dr Arnold's criticisms of the system, that bad, and obviously wrong data was being sent out.

Yes, it is implemented in quite a few systems. findu correctly interprets
this, if you look at the CW page for example:

<http://www.findu.com/cgi-bin/cw.cgi>

You see that some squares in the table, for example the baro at CW0012,
are blank, indicating a NULL value, something quite distinct from a zero.

That still happens, but often there are other reasons. For example, when a U2k powers up, until a calibration is entered, it sends bogus data. The sensor is there, so the is not sent, but the data is bad. If you look at a lot of the weather stations, there are lots of poorly maintained units out there that continue to send bad data. In the Keys, with the county owned weather system (W7IUC-*), only half are currently sending good data. Typically they rush to repair them when a storm is threatening, otherwise they ignore them.
